1 Causal Inference

In this chapter we want to give a introduction to causal inference. We particularly highlight the role of propensity score analysis and explain its importance in observational studies.

1.1 The Rubin Causal Model

from wiki: The Rubin causal model (RCM), also known as the Neyman–Rubin causal model,[1] is an approach to the statistical analysis of cause and effect based on the framework of potential outcomes, named after Donald Rubin. The name "Rubin causal model" was first coined by Paul W. Holland.[2] The potential outcomes framework was first proposed by Jerzy Neyman in his 1923 Master's thesis,[3] though he discussed it only in the context of completely randomized experiments.[4] Rubin extended it into a general framework for thinking about causation in both observational and experimental studies.[1]

1.2 Propensity Score Analysis

from wiki: In the statistical analysis of observational data, propensity score matching (PSM) is a statistical matching technique that attempts to estimate the effect of a treatment, policy, or other intervention by accounting for the covariates that predict receiving the treatment. PSM attempts to reduce the bias due to confounding variables that could be found in an estimate of the treatment effect obtained from simply comparing outcomes among units that received the treatment versus those that did not. Paul R. Rosenbaum and Donald Rubin introduced the technique in 1983.[1]

The possibility of bias arises because a difference in the treatment outcome (such as the average treatment effect) between treated and untreated groups may be caused by a factor that predicts treatment rather than the treatment itself. In randomized experiments, the randomization enables unbiased estimation of treatment effects; for each covariate, randomization implies that treatment-groups will be balanced on average, by the law of large numbers. Unfortunately,

for observational studies, the assignment of treatments to research subjects is typically not random. Matching attempts to reduce the treatment assignment bias, and mimic randomization, by creating a sample of units that received the treatment that is comparable on all observed covariates to a sample of units that did not receive the treatment.

For example, one may be interested to know the consequences of smoking. An observational study is required since it is unethical to randomly assign people to the treatment 'smoking.' The treatment effect estimated by simply comparing those who smoked to those who did not smoke would be biased by any factors that predict smoking (e.g.: gender and age). PSM attempts to control for these biases by making the groups receiving treatment and not-treatment comparable with respect to the control variables.

from a paper: Propensity score weighting is one of the techniques used in controlling for selection biases in non- experimental studies. Propensity scores can be used as weights to account for selection assignment differences between treatment and comparison groups. One of the advantages of this approach is that all the individuals in the study can be used for the outcomes evaluation

1.3 Weighting beyond the PS

from [WZ19]: Conventionally, the weights are estimated by modeling the propensities of receiving treatment or exhibiting missingness and then inverting the predicted propensities. However, with this approach it can be difficult to properly adjust for or balance the observed covariates. The reason is that this approach only balances covariates in expectation, by the law of large numbers, but in any particular data set it can be difficult to balance covariates, especially if the data set is small or if the covariates are sparse (Zubizarreta et al., 2011). In addition, this approach can result in very unstable estimates when a few observations have very large weights (e.g., Kang and Schafer 2007). To address these problems, a number of methods have been proposed recently. Instead of explicitly modeling the propensities of treatment or missingness, these methods directly balance the covariates. Some of these methods also minimize a measure of dispersion of the weights.

Most of these weighting methods balance covariates exactly rather than approximately. This is a subtle but important difference because approximate balance can trade bias for variance whereas exact balance cannot. Also, exact balance may not admit a solution whereas approximate balance may do so. For a fixed sample size, approximate balance may balance more functions of the

covariates than exact balance.

2 Balancing Weights

2.1 Introduction

We work in the Rubin Causal Model.

We assume a sample of n units which is drawn from a population distribution.

In i.i.d. fashion.

We observe (\mathbf{X}_i, T_i, Y_i) , where \mathbf{X} are covariates, T is the indicator if treatment has been received and Y is the observed outcome.

In the Rubin Causal Model we assume that for each unit the potential outcome exist, i.e. (Y_i^0, Y_i^1) where Y^1 stands for the potential outcome had the unit received treatment and Y^0 for the potential outcome had the unit received **no** treatment.

It is clear that $Y_i = Y_i^{T_i}$ i.e. we can observe only one of the potential outcomes.

Thus there is a connection to missing data problems.

This is the dilemma of causal inference.

On the population level it is possible to estimate both.

Usually the means of the potential outcomes are compared against each other.

In randomized trials this is a valid approach to causal inference.

In observational studies however the treatment assignment is not known and direct comparison can lead to systematically wrong results.

This phenomenon is called **confounding**.

To address the issue of confounding many methods have been proposed.

An intuitive way to think about potential outcomes is to think of a stochastic process $Y(\cdot)$ indexed over $\{0, 1\}$. By observing Y_i we in fact sample from this process at random index T , i.e. from $Y(T)$. We have

$$\mathbf{E}[Y(T)] = \mathbf{E}[Y(1)|T = 1]\mathbf{P}[T = 1] + \mathbf{E}[Y(0)|T = 0]\mathbf{P}[T = 0]. \quad (2.1)$$

Suppose we observe $T = 1$. Clearly we have

$$\mathbf{E}[Y(T)|T = 1] = \mathbf{E}[Y(1)|T = 1] \quad (2.2)$$

2.2 Double Robustness

2.2.1 Learning Rates of the weighted mean

What is the speed of convergence in the weak law of large numbers? The next statement gives a clear-cut answer: The arithmetic mean of independent, identically distributed, square-integrable random variables learns with rate $n^{-1/2}$. Furthermore, the statement is easy to prove using Bienaymé's formula and Chebyshev's inequality (cf. [Kle20, Theorem 5.14]).

Theorem. *Let X_1, X_2, \dots be i.i.d, square-integrable random variables with $V := \text{Var}[X_1] < \infty$. Then, for any $\tau \in (0, 1]$ and all $n \in \mathbb{N}$, we have*

$$\mathbf{P} \left[\left| \frac{1}{n} \sum_{i=1}^n (X_i - \mathbf{E}[X_i]) \right| \leq \sqrt{V} \frac{1}{\sqrt{\tau}} \frac{1}{\sqrt{n}} \right] \geq 1 - \tau. \quad (2.3)$$

What about more refined concentration inequalities?

Deriving learning rates in this way, we make an implicit assumption. We assume that observed outcomes of the treated follow the same distribution as marginal potential outcomes under treatment. In other words, we require

$$Y(1) | T = 1 \sim \mathbf{P}_{Y(1)}. \quad (2.4)$$

In practice, virtually every scenario violates this assumption. Indeed, any external influence on both T and $Y(1)$ can ruin the above assessment simply by imposing

$$\mathbf{E}[Y(T) | T = 1] \neq \mathbf{E}[Y(1)]. \quad (2.5)$$

Statisticians have wrestled with this issue for nearly a century.

In experimental studies we usually specify treatment assignment as opposed to merely observing a unit receiving treatment.

The next statement makes use of the propensity score.

Theorem. *Consider the weighted mean estimator with weights*

$$w_i = \frac{1}{n} \frac{T_i}{\pi(X_i)}. \quad (2.6)$$

Denote $V := \mathbf{E}[(Y(1))^2 / \pi(X)] - \mathbf{E}[Y(1)]^2$. Assume that weak unconfoundedness holds. Then, for any $\tau \in (0, 1]$ and all $n \in \mathbb{N}$, we have

$$\mathbf{P} \left[\left| \sum_{i=1}^n w_i Y_i - \mathbf{E}[Y(1)] \right| \leq \sqrt{V} \frac{1}{\sqrt{\tau}} \frac{1}{\sqrt{n}} \right] \geq 1 - \tau. \quad (2.7)$$

Proof. We want to reinforce coherent use of the weak law of large numbers. To this end, we verify

$$\begin{aligned} n \mathbf{E}[w(T, X) Y(T)] &= \mathbf{E}[Y(1)], \\ n^2 \mathbf{Var}[w(T, X) Y(T)] &= \mathbf{E}[(Y(1))^2 / \pi(X)] - \mathbf{E}[Y(1)]^2. \end{aligned}$$

Essentially, the random weight $w(T, X)$ acts on $Y(T)$ through $T / \pi(X)$. It does so by inducing independence of observed outcome $Y(T)$ and treatment T . This requires that weak unconfoundedness holds, i.e.,

$$(Y(0), Y(1)) \perp\!\!\!\perp T \mid X. \quad (2.8)$$

To showcase the details we added an n and n^2 factor in the above display. The calculations go as follows.

$$\begin{aligned} n \mathbf{E}[w(T, X) Y(T)] &= \mathbf{E}[Y(T) \cdot (T / \pi(X))] \\ &= \mathbf{E}[Y(1) / \pi(X) \mid T = 1] \cdot \mathbf{P}[T = 1] \\ &= \int_{\mathcal{X}} \mathbf{E}[Y(1) \mid X = x, T = 1] \cdot (\mathbf{P}[T = 1] / \pi(x)) \mathbf{P}_{X|T}(dx \mid 1) \\ &= \int_{\mathcal{X}} [Y(1) \mid X = x] \mathbf{P}_X(dx) = \mathbf{E}[Y(1)]. \end{aligned} \quad (2.9)$$

The first equality holds because of the definition of the weights. The second, third and last equality stem from $T \in \{0, 1\}$, and the law of total expectation, applied with T and X . The fourth equality is justified by the assumption of weak unconfoundedness. The density transformation is due to Bayes's Theorem. With slight modifications in the above argument, it follows

$$n^2 \mathbf{E} \left[\left(Y(T) \cdot (T / \pi(X)) \right)^2 \right] = \mathbf{E} \left[(Y(1))^2 / \pi(X) \right]. \quad (2.10)$$

We omit the details. Invoking the weak law of large numbers finishes the proof. \square

We started by asking an easy question, so it is time for a more challenging one: How do we proceed in deriving learning rates if the propensity score is unknown. How do we generally procede? [what has been done in the past. why are some methods obsolete] A naive answer would be: We hope to select a proper model and try to estimate the propensity score. Stunningly, a lot of practitioners still settle for obsolete methods when it comes to propensity score analysis.

2 Balancing Weights

Next, we consider the event that we have a consistent estimator of the propensity score and the distribution of the covariate vector X has compact support. In this case, there exists a constant $C_\pi \in (0, 1/2)$ such that

$$C_\pi \leq \pi(x) \leq 1 - C_\pi \quad \text{for all } x \in \mathcal{X}. \quad (2.11)$$

Furthermore,

$$\begin{aligned} & \sum_{i=1}^n w_i T_i Y_i - \mathbf{E}[Y(1)] \\ &= \frac{1}{n} \sum_{i=1}^n \frac{T_i}{\pi(X_i)} (Y_i - \mathbf{E}[Y(1)]) + \sum_{i=1}^n \left(w_i - \frac{1}{n} \frac{T_i}{\pi(X_i)} \right) Y_i. \end{aligned} \quad (2.12)$$

Previously we bounded the first term, so let us seek a bound for the second term. To this end, we shall use maximal inequalities from the theory of empirical processes. Consider

$$f_0(T, X, Y) := \quad (2.13)$$

The next assumptions reduce the technical task to a minimum.

Assumptions. (i)

2.3 Error Decompositions

The following decomposition is flexible in Φ . We get different causal estimands $\mathbf{E}[\Phi(Y(1))]$, e.g. the population average of $Y(1)$ for $\Phi(Y) = Y$, i.e. $\mathbf{E}[Y(1)]$, or the distribution function of $Y(1)$ at t for $\Phi(Y) = \mathbf{1}_{(-\infty, t]}(Y)$, i.e. $\mathbf{P}[Y(1) \leq t]$.

$$\sum_{i=1}^n w_i T_i \Phi(Y_i) - \mathbf{E}[\Phi(Y(1))] = \frac{1}{n} \sum_{i=1}^n S_i + R_0 + R_1 + R_2, \quad (2.14)$$

where

$$\begin{aligned} S_i &:= \frac{T_i}{\pi_i} (\Phi(Y_i) - \mathbf{E}[\Phi(Y_i(1))|X_i]) + (\mathbf{E}[\Phi(Y_i(1))|X_i] - \mathbf{E}[\Phi(Y(1))]) \quad \text{for } i \in \{1, \dots, n\}, \\ R_0 &:= \sum_{i=1}^n T_i \left(w_i - \frac{1}{n\pi_i} \right) (\Phi(Y_i) - \mathbf{E}[\Phi(Y_i(1))|X_i]), \\ R_1 &:= \sum_{i=1}^n \left(T_i w_i - \frac{1}{n} \right) (\mathbf{E}[\Phi(Y_i(1))|X_i] - B(X_i)^\top \lambda), \\ R_2 &:= \sum_{i=1}^n \left(T_i w_i - \frac{1}{n} \right) B(X_i)^\top \lambda \quad \text{for } \lambda \in \mathbb{R}^K. \end{aligned}$$

2.4 Estimating the Population Mean of Potential Outcomes

We can even view $\frac{1}{\sqrt{n}} \sum_{i=1}^n S_i$ as an empirical process $\mathbb{G}_n f$ indexed over

$$f_\Phi(T, X, Y) = \frac{T}{\pi(X)} (\Phi(Y) - \mathbf{E}[\Phi(Y)|X]) + \mathbf{E}[\Phi(Y)|X]. \quad (2.15)$$

If $\mathcal{F} = \{f_\Phi : \Phi \in \text{some set}\}$ is \mathbf{P} -Donsker, the empirical process converges to a tight gaussian process. Then the functional delta Method is applicable.

2.4 Estimating the Population Mean of Potential Outcomes

We want to estimate the population mean of the outcome under treatment, i.e. $\mathbf{E}[Y^1]$.

Since Y_i^1 is only observed for the treated units, i.e. if $T_i = 1$ we will consider a weighted mean of the observed outcomes as an estimator, i.e. $\hat{Y}_w^1 = \sum_{i=1}^n w_i T_i Y_i$ where we use convex optimization to compute the weights.

We consider the following decomposition

$$\hat{Y}_w^1 - \mathbf{E}[Y^1] = \frac{1}{n} \sum_{i=1}^n S_i + R_0 + R_1 + R_2, \quad (2.16)$$

where

$$\begin{aligned} S_i &:= \frac{T_i}{\pi_i} (Y_i - \mathbf{E}[Y_i^1|X_i]) + (\mathbf{E}[Y_i^1|X_i] - \mathbf{E}[Y^1]) \quad \text{for } i \in \{1, \dots, n\}, \\ R_0 &:= \sum_{i=1}^n T_i \left(w_i - \frac{1}{n\pi_i} \right) (Y_i - \mathbf{E}[Y_i^1|X_i]), \\ R_1 &:= \sum_{i=1}^n \left(T_i w_i - \frac{1}{n} \right) (\mathbf{E}[Y_i^1|X_i] - B(X_i)^\top \lambda) \quad \text{and} \quad R_2 := \sum_{i=1}^n \left(T_i w_i - \frac{1}{n} \right) B(X_i)^\top \lambda \quad \text{for } \lambda \in \mathbb{R}^K. \end{aligned}$$

We want to prove asymptotic normality

Theorem 2.1. *Suppose that conditions hold. Then*

$$\sqrt{n} (\hat{Y}_{w^*}^1 - \mathbf{E}[Y^1]) \xrightarrow{\mathcal{D}} Z \sim \mathcal{N}(0, \sigma_*^2).$$

To accomplish this we need

Theorem 2.2. *If $T_i = 1$ then $w^*(X_i)$ is a consistent estimator of $\frac{1}{n\pi(X_i)}$.*

We study the following problem:

Problem 2.1.

$$\underset{w_1, \dots, w_n \in \mathbb{R}}{\text{minimize}} \quad \sum_{i=1}^n T_i f(w_i)$$

subject to the constraints

$$w_i T_i \geq 0, \quad i = 1, \dots, n,$$

$$\sum_{i=1}^n w_i T_i = 1$$

$$\left| \sum_{i=1}^n w_i T_i B_k(X_i) - \frac{1}{n} \sum_{i=1}^n B_k(X_i) \right| \leq \delta_k, \quad k = 1, \dots, K$$

We aim to prove that the solution to Problem (??) is asymptotical consistent with the propensity score, i.e.

Theorem 2.3. *Under some (non-optimal) Assumptions, there exist constants $c_1, c_2 > 0$ and decreasing sequences $(\varepsilon_n^1), (\varepsilon_n^2) \subset (0, 1]$ that converge to 0 such that for all $\tau \in (0, 1]$ there exists a constant $c_\tau \in [0, \infty)$ only depending on τ such that for all $n \geq 1$ and $\tau \in (0, 1]$ it holds*

$$\begin{aligned} \mathbf{P} \left(\left\| w_i^* - \frac{1}{n\pi(X_i)} \right\|_\infty \leq c_1 c_\tau \varepsilon_n^1 \right) &\geq 1 - \tau, \\ \left\| w_i^* - \frac{1}{n\pi(X_i)} \right\|_{\mathbf{P}, 2} &\leq c_2 \varepsilon_n^2, \end{aligned} \tag{2.17}$$

where w^* is the solution to Problem (??).

Assumption 2.1. *Assume, the following conditions hold:*

2.1.1. *The minimizer $\lambda_0 = \arg \min_{\lambda \in \Theta} \mathbf{E} [-Tn\rho(B(X)^T \lambda) + B(X)^T \lambda]$ is unique, where $\Theta \subseteq \mathbb{R}^n$ is the parameter space for λ .*

2.1.2. *The parameter space $\Theta \subseteq \mathbb{R}^n$ is compact.*

2.4 Estimating the Population Mean of Potential Outcomes

2.1.3. $\lambda_0 \in \text{int}(\Theta)$, where $\text{int}(\cdot)$ stands for the interior of a set.

2.1.4. There exists $\lambda_1^* \in \Theta$ such that $\|m^*(\cdot) - B(\cdot)^T \lambda_1^*\|_\infty \leq \varphi_{m^*}$, where $m^*(\cdot) := \left(\rho'\right)^{-1} \left(\frac{1}{n\pi(\cdot)}\right)$.

2.1.5. There exists a constant $\varphi_\pi \in (0, \frac{1}{2})$ such that $\pi(x) \in (\varphi_\pi, 1 - \varphi_\pi)$ for all $x \in \mathcal{X}$

2.1.6. There exists $\varphi_{\rho''} > 0$ such that $-\rho'' \geq \varphi_{\rho''} > 0$

2.1.7. There exists $\varphi_{B(x)B(x)^T} > 0$ such that $B(x)B(x)^T \succcurlyeq \varphi_{B(x)B(x)^T} I$

2.1.8. There exists $\varphi_{\|B\|} > 0$ such that $\sup_{x \in \mathcal{X}} \|B(x)\|_2 \leq \varphi_{\|B\|}$.

2.1.9. The number of basis functions satisfies $K = o(n)$.

Plan of Proof

It is easier to study the dual of Problem (??). Thus we employ results from convex analysis [MMN22] to establish

Proposition 2.1. *The dual of Problem (??) is equivalent to the unconstrained optimization problem*

$$\underset{\lambda \in \mathbb{R}^K}{\text{minimize}} \quad \frac{1}{n} \sum_{j=1}^n [-T_j n \rho(B(X_j)^T \lambda) + B(X_j)^T \lambda] + |\lambda|^T \delta, \quad (2.18)$$

where $B(X_j) = (B_k(X_j))_{1 \leq k \leq K}$ denotes the K basis functions of the covariates, $\rho(t) := \frac{t}{n} - t(h')^{-1}(t) + h((h')^{-1}(t))$ with $h(x) := f\left(\frac{1}{n} - x\right)$ and $|\lambda| := (|\lambda_k|)_{1 \leq k \leq K}$. Moreover, the primal solution w_j^* satisfies

$$w_j^* = \rho' \left(B(X_j)^T \lambda^\dagger \right) \quad (2.19)$$

for $j = 1, \dots, n$, where λ^\dagger is the solution to the dual optimization problem.

The core of the subsequent analysis is based on Assumption 2.1.4, i.e. the existence of an oracle parameter λ_1^* in a sieve estimate of the true propensity score (or a transformation). It is then natural to enquire about the convergence of the dual solution λ^\dagger to λ_1^* . Making certain assumptions and employing matrix concentration inequalitys [Tro15] we can establish

2 Balancing Weights

Proposition 2.2. *Under some (non-optimal) Assumptions, there exists a constant $c_3 > 0$ and a decreasing sequence $(\varepsilon_n^3) \subset (0, 1]$ that converges to 0 such that for all $\tau \in (0, 1]$ there exists a constant $\tilde{c}_\tau \in [0, \infty)$ only depending on τ such that for all $n \geq 1$ and $\tau \in (0, 1]$ it holds*

$$\mathbf{P} \left(\left\| \lambda^\dagger - \lambda_1^* \right\|_2 \leq c^3 \tilde{c}_\tau (\varepsilon_n^3) \right) \geq 1 - \tau. \quad (2.20)$$

It is then straightforward to prove a more general result than Theorem 2.3.

Theorem 2.4. *Under some (non-optimal) Assumptions, there exist constants $c_1, c_2 > 0$ and decreasing sequences $(\varepsilon_n^1), (\varepsilon_n^2) \subset (0, 1]$ that converge to 0 such that for all $\tau \in (0, 1]$ there exists a constant $c_\tau \in [0, \infty)$ only depending on τ such that for all $n \geq 1$ and $\tau \in (0, 1]$ it holds*

$$\begin{aligned} \mathbf{P} \left(\left\| w^*(\cdot) - \frac{1}{n\pi(\cdot)} \right\|_\infty \leq c_1 c_\tau \varepsilon_n^1 \right) &\geq 1 - \tau, \\ \left\| w^*(X) - \frac{1}{n\pi(X)} \right\|_{\mathbf{P}, 2} &\leq c_2 \varepsilon_n^2, \end{aligned}$$

where $w^*(X)$ is as in (2.19) without the index.

Proof of theorem 2.2

Proof. Motivated by Proposition 3.2 we consider

$$G(\lambda) := \frac{1}{n} \sum_{j=1}^n [-T_j n \rho(B(X_j)^T \lambda) + B(X_j)^T \lambda] + |\lambda|^T \delta. \quad (2.21)$$

2.4 Estimating the Population Mean of Potential Outcomes

Since $\rho \in C^2(\mathbb{R})$ we can employ (2.21), Corollary 6.1.1 and Proposition 6.1 to get

$$\begin{aligned}
& G(\lambda_1^* + \Delta) - G(\lambda_1^*) \\
& \geq \frac{1}{n} \sum_{j=1}^n \left[-T_j n \rho' (B(X_j)^T \lambda_1^*) + 1 \right] \Delta^T B(X_j) \\
& \quad + \frac{1}{2} \sum_{j=1}^n -T_j \rho'' (B(X_j)^T (\lambda_1^* + \xi \Delta)) \Delta^T (B(X_j) B(X_j)^T) \Delta \\
& \quad - |\Delta|^T \delta \\
& \geq -\|\Delta\|_2 \left(\left\| \frac{1}{n} \sum_{j=1}^n \left[-T_j n \rho' (B(X_j)^T \lambda_1^*) + 1 \right] B(X_j) \right\|_2 + \|\delta\|_2 \right) \\
& \quad + n \|\Delta\|_2^2 \varphi_{\rho''} \varphi_{BB^T} \\
& := -\|\Delta\|_2 (I_1 + \|\delta\|_2) + \|\Delta\|_2^2 I_2.
\end{aligned} \tag{2.22}$$

The second inequality is due to the Cauchy-Schwarz-Inequality and Assumptions 2.1.6 and 2.1.7. We want to establish probabilistic upper bounds of the factor associated with $-\|\Delta\|_2$. This will be done with appropriate assumptions on $\|\delta\|_2$ and a thorough analysis of I_1 . If we then restrict lower bounds of I_2 to appropriately slow convergence to 0, e.g. by assumptions on $\varphi_{\rho''}$ and φ_{BB^T} , we can choose $\|\Delta\|_2$ large enough, such that (2.22) yields $G(\lambda_1^* + \Delta) - G(\lambda_1^*) > 0$ with arbitrarily large probability for n large enough. With Proposition 3.2 it follows then immediately Proposition 2.2.

Analysis of I_1

We want to use Assumption 2.1.3. Thus we perform the following split:

$$\begin{aligned}
I_1 & \leq \left\| \sum_{j=1}^n T_j \left[\rho' (B(X_j)^T \lambda_1^*) - \frac{1}{n\pi(X_j)} \right] B(X_j) \right\|_2 \\
& \quad + \left\| \frac{1}{n} \sum_{j=1}^n \left[\frac{T_j}{\pi(X_j)} - 1 \right] B(X_j) \right\|_2 \\
& =: J_1 + J_2
\end{aligned} \tag{2.23}$$

Analysis of J_1

By the Lipschitz-continuity of ρ' , Assumption 2.1.8 and Assumption 2.1.4, $T \in \{0, 1\}$ and the triangle inequality we have

$$J_1 \leq nL_{\rho'} \varphi_{\|B(x)\|} \varphi_{m^*} \quad (2.24)$$

Analysis of J_2

We want to employ Theorem ?? . To this end we define the independent random matrices

$$\begin{aligned} A_j &:= \frac{1}{n} \left[\frac{T_j}{\pi(X_j)} - 1 \right] B(X_j), \quad j = 1, \dots, n, \\ S &:= \sum_{j=1}^n A_j \end{aligned} \quad (2.25)$$

and check conditions (??) and (4.31). Note that $\|S\|_2 = J_2$. By the properties of conditional expectation it holds

$$\mathbf{E} \left[\frac{T_j}{\pi(X_j)} B(X_j) \right] = \mathbf{E} \left[\mathbf{E}[T_j | X_j] \frac{1}{\pi(X_j)} B(X_j) \right] = \mathbf{E}[B(X_j)]. \quad (2.26)$$

Taking the expectation in (2.25) and using (2.26) we get $\mathbf{E}[A_j] = 0$ for all $j = 1, \dots, n$. Since

$$\left| \frac{T_j}{\pi(X_j)} - 1 \right| \leq 1 + \frac{1 - \varphi_\pi}{\varphi_\pi} = \frac{1}{\varphi_\pi} \quad (2.27)$$

by Assumption 2.1.5, we can employ Assumption 2.1.8 together with (2.27) and (2.25) to get

$$\|A_j\|_2 \leq \frac{\varphi_{\|B\|}}{n\varphi_\pi} =: L. \quad (2.28)$$

Thus, condition (??) is satisfied. Next we turn to the matrix variance statistic $v(S)$ (4.31). By (2.25) and (2.27) we have

$$\mathbf{E} [A_j A_j^T] \leq \left(\frac{1}{n\varphi_\pi} \right)^2 \mathbf{E} [B(X) B(X)^T] \quad (2.29)$$

and by (2.28)

$$\mathbf{E} [A_j^T A_j] \leq L^2. \quad (2.30)$$

2.4 Estimating the Population Mean of Potential Outcomes

Since $\max\{a, b\} \leq |a| + |b|$ we can use (2.29) and (2.30) to get

$$v(S) \leq \frac{1}{n} \frac{\lambda_{\max}}{\varphi_{\pi}^2} + nL^2, \quad (2.31)$$

where λ_{\max} is the maximal eigenvalue of the symmetric (non-random) matrix $\mathbf{E}[B(X)B(X)^T]$. Having dealt with (??) and (4.31) we can establish the expectation bound (??) of Theorem ??. Together with (2.28) and (2.31) we get

$$\begin{aligned} & \mathbf{E}[J_2] \\ & \leq \sqrt{\frac{2 \log(K+1) (\lambda_{\max} + \varphi_{\|B\|}^2)}{n \varphi_{\pi}^2}} + \frac{\log(K+1) \varphi_{\|B\|}}{3n \varphi_{\pi}} \\ & \leq \frac{1}{\varphi_{\pi}} \sqrt{\frac{\log(K+1)}{n}} \left[\varphi_{\|B\|} \left(\sqrt{2} + \frac{1}{3} \sqrt{\frac{\log(K+1)}{n}} \right) + \sqrt{2\lambda_{\max}} \right]. \end{aligned} \quad (2.32)$$

Since $K = o(n)$ by Assumption 2.1.9 we can discuss the other influences on the quality of the bound (2.32). On a high-level it is readily clear that appropriate bounds on φ_{π} , $\varphi_{\|B\|}$ and λ_{\max} will shrink $\mathbf{E}[J_2]$ to 0 and will assist in establishing learning rates.

We could also have invoked the probability bound (??) of Theorem ??. But for the sake of simplicity we prefer the combination of the expectation bound (2.32) and the Markov inequality. With the latter we get

$$J_2 \leq \frac{1}{\tau} \frac{1}{\varphi_{\pi}} \sqrt{\frac{\log(K+1)}{n}} \left[\varphi_{\|B\|} \left(\sqrt{2} + \frac{1}{3} \sqrt{\frac{\log(K+1)}{n}} \right) + \sqrt{2\lambda_{\max}} \right] \quad (2.33)$$

with probability $\geq 1 - \tau$.

If we choose $\|\Delta\|_2$ to be

$$\begin{aligned} & \left(\sqrt{2} \frac{1}{\tau} \frac{1}{\varphi_{\pi}} \sqrt{\frac{\log(K+1)}{n^3}} \left[\varphi_{\|B\|} \left(1 + \sqrt{\frac{\log(K+1)}{n}} \right) + \sqrt{\lambda_{\max}} \right] \right. \\ & \quad \left. + L_{\rho'} \varphi_{\|B\|} \varphi_{m^*} + \frac{\|\delta\|_2}{n} \right) \frac{1}{\varphi_{\rho''} \varphi_{BB^T}} \end{aligned} \quad (2.34)$$

we get by (2.22), (2.23), (2.24), (2.33) and Proposition 3.2

$$\begin{aligned} \mathbf{P} \left(\left\| \lambda^{\dagger} - \lambda_1^* \right\|_2 \leq C \right) &= \mathbf{P} \left(\inf_{\|\Delta\|_2=C} G(\lambda_1^* + \Delta) - G(\lambda_1^*) > 0 \right) \\ &\geq 1 - \tau, \end{aligned} \quad (2.35)$$

2 Balancing Weights

where C is as in (2.34). With appropriate Assumptions (as discussed before) we can then establish Proposition 2.2.

We can invoke (2.35) to derive bounds as in Theorem 2.17:

$$\begin{aligned} \left\| w^*(X) - \frac{1}{n\pi(X)} \right\|_{\mathbf{P},2} &\leq L_{\rho'} \left[\left\| B(X)^T (\lambda^\dagger - \lambda_1^*) \right\|_{\mathbf{P},2} \right. \\ &\quad \left. + \left\| m^*(X) - B(X)^T \lambda_1^* \right\|_{\mathbf{P},2} \right] \\ &\leq L_{\rho'} \left(\varphi_{\|B\|} \sqrt{C^2(1-\tau) + \text{diam}(\Theta)^2\tau} + \varphi_{m^*} \right) \end{aligned}$$

$$\begin{aligned} \left\| w^*(\cdot) - \frac{1}{n\pi(\cdot)} \right\|_{\infty} &\leq L_{\rho'} \left[\left\| B(\cdot)^T (\lambda^\dagger - \lambda_1^*) \right\|_{\infty} \right. \\ &\quad \left. + \left\| m^*(\cdot) - B(\cdot)^T \lambda_1^* \right\|_{\infty} \right] \\ &\leq L_{\rho'} (\varphi_{\|B\|} C + \varphi_{m^*}) \end{aligned}$$

with probability greater than $1 - \tau$. \square

Remark 2.1. *By Corollary ?? we can get rid of the $\log(K)$ term in (2.34).* \diamond

Remark 2.2. *By the matrix Rosenthal-Pinelis Inequality [CGT12]/[Thm.A.1] we can weaken Assumption 2.1.5 to a lower bound on the expectation of $\pi(X)$* \diamond

The next step consists of strengthening the Assumptions to get concrete learning rates. This can be done in a series of examples.

2.5 Application of Convex Optimization

Assumption 2.2. *Assume that the map $f : \mathbb{R} \rightarrow \overline{\mathbb{R}}$ has the following properties.*

- (i) *f is strictly convex.*
- (ii) *f is lower-semicontinuous and continuously differentiable on $\text{int}(\text{dom}(f))$.*
- (iii) *The derivative of f on $\text{int}(\text{dom}(f))$ is a diffeomorphism.*
- (iv) *The Legendre transformation f^* of f is finite.*
- (v) *The function $x \mapsto xt - f(x)$ takes its supremum on $\text{int}(\text{dom}(f))$ for all $t \in \mathbb{R}$.*

We consider the following optimization problem.

Problem 2.2.

$$\underset{w_1, \dots, w_n \in \mathbb{R}}{\text{minimize}} \quad \sum_{i=1}^n T_i f(w_i)$$

subject to the constraints

$$\begin{aligned} w_i T_i &\geq 0, & i = 1, \dots, n, \\ \sum_{i=1}^n w_i T_i &= 1 \\ \left| \sum_{i=1}^n w_i T_i B_k(X_i) - \frac{1}{n} \sum_{i=1}^n B_k(X_i) \right| &\leq \delta_k, & k = 1, \dots, K \end{aligned}$$

Theorem 2.5. *Under Assumption, the dual of the above Problem is the unconstrained optimization problem*

$$\underset{\lambda \in \mathbb{R}^K}{\text{minimize}} \quad \frac{1}{n} \sum_{i=1}^n nT_i f^*(\langle B(X_i), \lambda \rangle) - \langle B(X_i), \lambda \rangle + \langle \delta, |\lambda| \rangle,$$

where $t \mapsto f^*(t) = t(f')^{-1}(t) - f((f')^{-1}(t))$ is the Legendre transformation of f , $B(X_i) = [B_1(X_i), \dots, B_K(X_i)]^\top$ denotes the K basis functions of the covariates of unit $i \in \{1, \dots, n\}$ and $|\lambda| = [|\lambda_1|, \dots, |\lambda_K|]^\top$, where $|\cdot|$ is the absolute value of a real-valued scalar. Moreover, if λ^\dagger is an optimal solution then

$$w_i^* = (f')^{-1}(\langle B(X_i), \lambda^\dagger \rangle), \quad i \in \{1, \dots, n\} \quad (2.36)$$

are the unique optimal solutions to (P).

Proof. We prove the following Lemma at the end of the section.

Lemma 2.1. *The dual of the optimization problem is*

$$\underset{\lambda \in \mathbb{R}^{2K}}{\text{minimize}} \quad \frac{1}{n} \sum_{i=1}^n nT_i f^*(\langle Q_{\bullet i}, \lambda \rangle) - \langle Q_{\bullet i}, \lambda \rangle + \langle d, \lambda \rangle$$

subject to

$$\lambda_k \geq 0 \quad \text{for all } k \in \{1, \dots, K\}, \quad (2.37)$$

where

$$\mathbf{Q} := \begin{bmatrix} \mathbf{I}_n \\ \mathbf{B}(\mathbf{X}) \\ -\mathbf{B}(\mathbf{X}) \end{bmatrix}, \quad \mathbf{B}(\mathbf{X}) := [B(X_1), \dots, B(X_n)], \quad \text{and} \quad d := \begin{bmatrix} 0_n \\ \delta \\ \delta \end{bmatrix}. \quad (2.38)$$

2.6 Application of Matrix Concentration Inequalities

Proof. *Lemma* We write the optimization problem in the form of [TB91].

$$\underset{w_1, \dots, w_n \in \mathbb{R}}{\text{minimize}} \quad \sum_{i=1}^n T_i f(w_i) \quad (2.39)$$

$$w_i T_i \geq 0, \quad i = 1, \dots, n, \quad (2.40)$$

$$\sum_{i=1}^n w_i T_i = 1 \quad (2.41)$$

$$\sum_{i=1}^n w_i T_i B_k(X_i) \geq -\delta_k + \frac{1}{n} \sum_{i=1}^n B_k(X_i) \quad k = 1, \dots, K \quad (2.42)$$

$$-\sum_{i=1}^n w_i T_i B_k(X_i) \geq -\delta_k - \frac{1}{n} \sum_{i=1}^n B_k(X_i) \quad k = 1, \dots, K \quad (2.43)$$

Next we write

$$\mathbf{Q} := \begin{bmatrix} \text{diag}[T_1, \dots, T_n] \\ \mathbf{B}(\mathbf{X}) \\ -\mathbf{B}(\mathbf{X}) \end{bmatrix}, \quad \mathbf{B}(\mathbf{X}) := [T_1 B(X_1), \dots, T_n B(X_n)], \quad \text{and} \quad d := \begin{bmatrix} 0_n \\ -\delta + \overline{B(\mathbf{X})} \\ -\delta - \overline{B(\mathbf{X})} \end{bmatrix}, \quad (2.44)$$

where $\overline{B(\mathbf{X})} := [\overline{B_1(\mathbf{X})}, \dots, \overline{B_K(\mathbf{X})}]^\top$ and $\overline{B_k(\mathbf{X})} := \frac{1}{n} \sum_{i=1}^n B_k(X_i)$. We get

$$\underset{w_1, \dots, w_n \in \mathbb{R}}{\text{minimize}} \quad \sum_{i=1}^n T_i f(w_i) \quad (2.45)$$

$$1_n \cdot w = 0 \quad (2.46)$$

$$\mathbf{Q}w \geq d \quad (2.47)$$

The convex conjugate is

$$\sum_{T_i=1} T_i f^*(\lambda_i) + \sum_{T_i=0} \delta_{\{0\}}(\lambda_i). \quad (2.48)$$

Since $\mathbf{Q}_{\bullet i} = 0_n$ if $T_i = 0$ we get the desired representation. Note that the equality constraint vanishes automatically. \square

\square

2.6 Application of Matrix Concentration Inequalities

Analysis of $\mathbf{E}[\max_{i \leq n} \|A_i\|^2]$

We start from the premise that the fourth moment of the random quantities $B_k(X_i)$ and $1/\pi_i$ is uniformly bounded in k and i .

2 Balancing Weights

Assumptions. (i) *There exists a constant $C_B \geq 1$ such that*

$$\mathbf{E} [B_k(X_i)^4] \leq C_B \quad \text{for all } (k, i) \in \{1, \dots, K\} \times \{1, \dots, n\}.$$

(ii) *There exists a constant $C_\pi \geq 1$ such that*

$$\mathbf{E} \left[\left(\frac{1}{\pi_i} \right)^4 \right] \leq C_\pi \quad \text{for all } i \in \{1, \dots, n\}.$$

Note, that these assumptions allow for covariate distributions with unbounded support. The coming example ought to reinforce this observation.

Example. Let us assume a logistic regression model for the propensity score. Then there exist coefficients $\vartheta \in \mathbb{R}^N$ and $\vartheta_0 \in \mathbb{R}$ (N is the number of covariates and ϑ_0 is the intercept of the model) such that

$$1 / \pi(X) = 1 + \exp(\vartheta_0 + \langle \vartheta, X \rangle), \quad (2.49)$$

$$\mathbf{E} \left[\left(\frac{1}{\pi(X)} \right)^4 \right] = \sum_{j=1}^4 \binom{4}{j} e^{j\vartheta_0} M_X(j\vartheta), \quad (2.50)$$

where M_X is the moment-generating function of the random vector X (we assume it exists.). While the quantity in (2.49) may be unbounded when X has unbounded support, that in (2.50) remains bounded for moderate decay rates of the underlying distribution.

The multivariate normal distribution with location parameter $\mu \in \mathbb{R}^N$ and covariance matrix $\Sigma \in \mathbb{M}_N$ has moment-generating function

$$M_{\mathcal{N}(\mu, \Sigma)}(t) = \exp \left(\langle t, \mu \rangle + \frac{\langle t, \Sigma t \rangle}{2} \right) \quad \text{for all } t \in \mathbb{R}^N.$$

In particular, the expression in (2.50) is finite if X follows a multivariate normal distribution.

Likewise we give a negative example. Let $N = 1$ and $X \sim \text{Exp}(\lambda)$, that is, only one exponentially distributed covariate is taken into account. The moment-generating function is then confined to take arguments $t < \lambda$, and thus (2.50) becomes pointless if $4\vartheta \geq \lambda$. \diamond

Next, we recall the entity we want to examine.

$$A_i = \frac{1}{n} \left(1 - \frac{T_i}{\pi_i} \right) B(X_i) \quad \text{for } i \in \{1, \dots, n\}.$$

2.6 Application of Matrix Concentration Inequalities

For all $i \in \{1, \dots, n\}$ we get the bound

$$\left| 1 - \frac{T_i}{\pi_i} \right| \leq \left(1 \vee \frac{1 - \pi_i}{\pi_i} \right) \leq 1 + \frac{1 - \pi_i}{\pi_i} = \frac{1}{\pi_i}. \quad (2.51)$$

Let $i^* \in \{1, \dots, n\}$ be the index where $\|A_i\|$ attains its maximum.

$$\begin{aligned} \mathbf{E} \left[\max_{i \leq n} \|A_i\|^2 \right] &= \mathbf{E} \left[\|A_{i^*}\|^2 \right] \leq \mathbf{E} \left[\left(\frac{\|B(X_{i^*})\|}{\pi_{i^*}} \right)^2 \right] / n^2 \\ &\leq \mathbf{E} \left[\left(\frac{1}{\pi_{i^*}} \right)^4 \right]^{1/2} \cdot \mathbf{E} \left[\|B(X_{i^*})\|^4 \right]^{1/2} / n^2 \\ &\leq K / n^2 \cdot \sqrt{C_\pi C_B}. \end{aligned} \quad (2.52)$$

The first inequality comes from the bound (2.51). The Cauchy-Schwarz inequality provides the second inequality. In the last step we use the assumptions made at the start of the section. Paying the price of an extra n factor, the maximal inequality (2.52) yields a bound of the sum, that is,

$$\sum_{i=1}^n \mathbf{E} \left[\|A_i\|^2 \right] \leq \frac{K}{n} \sqrt{C_\pi C_B} \quad (2.53)$$

Assumption 2.3. .

Assumption 2.4. .

Remark 2.3. *With Assumption we also get a bound on the fourth moment of $\|B(X_i)\|$. Indeed, by the convexity of $x \mapsto x^2$, the monotonicity and linearity of the expectation it holds*

$$\begin{aligned} \mathbf{E}[\|B(X_i)\|^4] &= \mathbf{E} \left[\left(\sum_{k=1}^K B_k^2(X_i) \right)^2 \right] = K^2 \mathbf{E} \left[\left(\sum_{k=1}^K \frac{1}{K} B_k^2(X_i) \right)^2 \right] \leq K^2 \mathbf{E} \left[\sum_{k=1}^K \frac{1}{K} B_k^4(X_i) \right] \\ &= K \sum_{k=1}^K \mathbf{E} [B_k^4(X_i)] \leq K^2 C_B \end{aligned} \quad (2.54)$$

◇

2 Balancing Weights

Analysis of $v(\mathbf{S})$

We use the fact that $\|A\|_2 \leq \|A\|_F = \sqrt{\sum_{i,j} a_{ij}^2}$. It holds

$$\sum_{i=1}^n \mathbf{E}[A_i A_i^\top] = \frac{1}{n^2} \sum_{i=1}^n \mathbf{E} \left[\left(\frac{1-\pi_i}{\pi_i} \right)^2 B(X_i) B(X_i)^\top \right] = \frac{1}{n^2} \left(\sum_{i=1}^n \mathbf{E} \left[\left(\frac{1-\pi_i}{\pi_i} \right)^2 B_k(X_i) B_l(X_i) \right] \right)_{1 \leq k, l \leq K} \quad (2.55)$$

Thus

$$\begin{aligned} & \left\| \sum_{i=1}^n \mathbf{E}[A_i A_i^\top] \right\|_2^2 \\ & \leq \left\| \sum_{i=1}^n \mathbf{E}[A_i A_i^\top] \right\|_F^2 = \frac{1}{n^4} \sum_{k,l=1}^K \left(\sum_{i=1}^n \mathbf{E} \left[\left(\frac{1-\pi_i}{\pi_i} \right)^2 B_k(X_i) B_l(X_i) \right] \right)^2 \\ & \leq \frac{1}{n^4} \sum_{k,l=1}^K \left(\sum_{i=1}^n \mathbf{E} \left[\left(\frac{1-\pi_i}{\pi_i} \right)^4 \right]^{\frac{1}{2}} \mathbf{E}[B_k(X_i)^4]^{\frac{1}{4}} \mathbf{E}[B_l(X_i)^4]^{\frac{1}{4}} \right)^2 \leq \left(\frac{K}{n} \right)^2 C_\pi C_B \end{aligned} \quad (2.56)$$

On the other hand

$$\begin{aligned} \left\| \sum_{i=1}^n \mathbf{E}[A_i^\top A_i] \right\|_2 &= \sum_{i=1}^n \mathbf{E}[A_i^\top A_i] = \frac{1}{n^2} \sum_{i=1}^n \mathbf{E} \left[\left(\frac{1-\pi_i}{\pi_i} \right)^2 \|B(X_i)\|_2^2 \right] \\ &\leq \frac{1}{n^2} \sum_{i=1}^n \mathbf{E} \left[\left(\frac{1-\pi_i}{\pi_i} \right)^4 \right]^{\frac{1}{2}} \|B(X_i)\|_2^2 \leq \frac{K}{n} \sqrt{C_\pi C_B} \end{aligned} \quad (2.57)$$

It follows

$$v(\mathbf{S}) \leq \frac{K}{n} \sqrt{C_\pi C_B} \quad (2.58)$$

Thus we can apply Theorem 4.4 to get

$$\mathbf{E}[\|\mathbf{S}\|_2] \leq \sqrt{2e \frac{K}{n} \sqrt{C_\pi C_B} \log(K+1)} + 4e \frac{\sqrt{K}}{n} \sqrt[4]{C_\pi C_B} \log(K+1) \leq 14C_\pi C_B \sqrt{\frac{K \log(K+1)}{n}} \quad (2.59)$$

3 Convex Analysis

In our application we want to analyze a convex optimization problem by its dual problem. In particular we want to obtain primal optimal solutions from dual solutions. To accomplish the task we need technical tools from convex analysis, mainly conjugate calculus and some KKT related results.

Our starting point is the support function intersection rule, which we will prove in full detail employing a theorem on convex separation in finite dimensions. To this end, we will have a closer look in relative interiors and support functions. As an application we may prove the conjugate chain and sum rule, which are vital to application of duality. As a simple corollary we will obtain the classical Fenchel-Rockafellar Duality theorem which gives general conditions for dual and primal optimal values to be equal.

The material we present is very well known, so we claim no originality. We orient our exposition closely by [Roc70, MMN22].

We finish the chapter with an exposition of [TB91], where for strictly convex functions we get a dual relationship in terms of the optimal solutions.

3.1 A Convex Analysis Primer

Excursively, we present some well known definitions and facts from convex analysis. For details, see, e.g., [MMN22].

A subset $C \subseteq \mathbb{R}^n$ is called **convex set**, if for all $x, y \in C$ and all $\lambda \in [0, 1]$, we have $\lambda x + (1 - \lambda)y \in C$. The Cartesian product of convex sets is convex. The intersection of a collection of convex sets is also convex.

Given (not necessary convex) sets $\Omega, \Omega_1, \Omega_2 \subseteq \mathbb{R}^n$ and $\lambda \in \mathbb{R}$, define the **set addition** and **multiplication** by a real scalar as $\Omega_1 + \Omega_2 := \{x_1 + x_2 : x_1 \in \Omega_1, x_2 \in \Omega_2\}$ and $\lambda\Omega := \{\lambda x : x \in \Omega\}$. For convex sets the addition and multiplication by a real scalar are convex.

Throughout this section, we shall denote by $B := \{x = [x_1, \dots, x_n]^\top \in \mathbb{R}^n : (\sum_{i=1}^n x_i^2)^{1/2} \leq 1\}$

Solve editorial issue with ball.

3 Convex Analysis

the **Euclidian unit ball** in \mathbb{R}^n . This is a closed convex set. For any $a \in \mathbb{R}^n$, the **ball with radius $\varepsilon > 0$ and center a** is given by $\{a + x \in \mathbb{R}^n : (\sum_{i=1}^n x_i^2)^{1/2} \leq \varepsilon\} = a + \varepsilon B$. For any set Ω in \mathbb{R}^n , the set of points x whose distance from Ω does not exceed ε is $\Omega + \varepsilon B$. The **closure** $\text{cl}(\Omega)$ and **interior** $\text{int}(\Omega)$ of Ω can therefore be expressed by $\text{cl}(\Omega) = \bigcap_{\varepsilon > 0} \Omega + \varepsilon B$ and $\text{int}(\Omega) = \{x \in \Omega : \text{there exists } \varepsilon > 0 \text{ such that } x + \varepsilon B \subseteq \Omega\}$.

A set $A \subseteq \mathbb{R}^n$ is called **affine set**, if $\alpha x + (1 - \alpha)y \in A$ for all $x, y \in A$ and $\alpha \in \mathbb{R}$. The **affine hull** $\text{aff}(\Omega)$ of a set $\Omega \subseteq \mathbb{R}^n$ is the smallest affine set that includes Ω . A mapping $A : \mathbb{R}^n \rightarrow \mathbb{R}^m$ is called **affine mapping** if there exist a linear mapping $L : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and a vector $b \in \mathbb{R}^m$ such that $A(x) = L(x) + b$ for all $x \in \mathbb{R}^n$. The image and inverse image/preimage of convex sets under affine mappings are also convex.

Because the notion of interior is not precise enough for our purposes we define the relative interior which is the interior relative to the affine hull. This concept is motivated by the fact that a line segment embedded in \mathbb{R}^2 does have a natural interior in \mathbb{R} which is not a true interior in \mathbb{R}^2 . The relative interior of C is defined as the interior which results when C is regarded as a subset of its affine hull.

Definition 3.1. Let $\Omega \subseteq \mathbb{R}^n$. We define the **relative interior** of Ω by

$$\text{ri}(\Omega) := \{x \in \Omega : \text{there exists } \varepsilon > 0 \text{ such that } (x + \varepsilon B) \cap \text{aff}(\Omega) \subset \Omega\}. \quad (3.1)$$

Next we collect some useful properties of relative interiors.

Proposition 3.1. Let C be a non-empty convex set in \mathbb{R}^n . Then we get the representation

- (i) $\text{ri}(C) = \{z \in C : \text{for all } x \in C \text{ there exists } t > 0 \text{ such that } z + t(z - x) \in C\}$.
- (ii) $\text{ri}(C) \neq \emptyset$ if $C \neq \emptyset$.
- (iii) $\text{cl}(C)$ and $\text{ri}(C)$ are convex sets.
- (iv) $\text{cl}(\text{ri}(C)) = \text{cl}(C)$ and $\text{ri}(\text{cl}(C)) = \text{ri}(C)$.
- (v) Suppose $\bigcap_{i \in I} C_i \neq \emptyset$ for a finite index set I . Then $\text{ri}(\bigcap_{i \in I} C_i) = \bigcap_{i \in I} \text{ri}(C_i)$.
- (vi) Let $L : \mathbb{R}^n \rightarrow \mathbb{R}^m$ be a linear mapping. Then $\text{ri}(L(C)) = L(\text{ri}(C))$. If additionally it holds $L^{-1}(\text{ri}(C)) \neq \emptyset$ we have $\text{ri}(L^{-1}(C)) = L^{-1}(\text{ri}(C))$.
- (vii) $\text{ri}(C_1 \times C_2) = \text{ri}(C_1) \times \text{ri}(C_2)$.
- (viii) $\text{ri}(C_1) \cap \text{ri}(C_2) = \emptyset$ if and only if $0 \notin \text{ri}(C_1 - C_2)$.

Order results to give pretty proof.

Proof. (i) [Roc70, Theorem 6.4]

(ii) [Roc70, Theorem 6.2]

(iii) [Roc70, Theorem 6.2]

(iv) [Roc70, Theorem 6.3]

(v) [Roc70, Theorem 6.5]

(vi) [Roc70, Theorem 6.6-6.7]

(vii) Let $(z_1, z_2) \in \text{ri}(C_1 \times C_2)$. Then for all $(x_1, x_2) \in C_1 \times C_2$ there exists $t > 0$ such that

$$z_i + t(z_i - x_i) \in C_i \quad \text{for } i \in \{1, 2\}. \quad (3.2)$$

This proves \subseteq . Suppose $z_1 \in \text{ri}(C_1)$ and $z_2 \in \text{ri}(C_2)$. Let $(x_1, x_2) \in C_1 \times C_2$ with If $t_1 = t_2$ everything is clear. W.l.o.g. assume $t_1 < t_2$. Define $\theta := \frac{t_1}{t_2} \in (0, 1)$. By the convexity of C_2 it follows

$$z_2 + t_1(z_2 - x_2) = \theta(z_2 + t_2(z_2 - x_2)) + (1 - \theta)z_2 \in C_2. \quad (3.3)$$

Thus $(z_1, z_2) \in \text{ri}(C_1 \times C_2)$. This proves \supseteq and equality.

(viii) [MMN22, Theorem 2.92]

□

We proceed with convex separation results which are vital to the subsequent developments.

Definition 3.2. Let C_1 and C_2 be two non-empty convex sets in \mathbb{R}^n . A hyperplane H is said to **separate** C_1 and C_2 if C_1 is contained in one of the closed half-spaces associated with H and C_2 lies in the opposite closed half-space. It is said to separate C_1 and C_2 **properly** if C_1 and C_2 are not both actually contained in H itself.

Theorem 3.1. Let C_1 and C_2 be two non-empty convex sets in \mathbb{R}^n . There exists a hyperplane separating C_1 and C_2 properly if and only if there exists a vector $b \in \mathbb{R}^n$ such that

$$\sup_{x \in C_2} \langle x, b \rangle \leq \inf_{x \in C_1} \langle x, b \rangle \quad \text{and} \quad \inf_{x \in C_2} \langle x, b \rangle < \sup_{x \in C_1} \langle x, b \rangle. \quad (3.4)$$

Proof. [Roc70, Theorem 11.1] □

Theorem 3.2. (Convex separation in finite dimension) *Let C_1 and C_2 be two non-empty convex sets in \mathbb{R}^n . Then C_1 and C_2 can be properly separated if and only if $\text{ri}(C_1) \cap \text{ri}(C_2) = \emptyset$.*

Proof. [Roc70, Theorem 11.3] □

Definition 3.3. *Given a nonempty subset $\Omega \subseteq \mathbb{R}^n$ the **support function** $\sigma_\Omega : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ of Ω is defined by*

$$\sigma_\Omega(x^*) := \sup_{x \in \Omega} \langle x^*, x \rangle \quad \text{for } x^* \in \mathbb{R}^n. \quad (3.5)$$

Definition 3.4. *Given functions $f_i : \mathbb{R}^n \rightarrow (-\infty, \infty]$ for $i = 1, \dots, n$ the **infimal convolution** of these functions is defined as*

$$(f_1 \square \dots \square f_m)(x) := \inf_{\substack{x_i \in \mathbb{R}^n \\ \sum_{i=1}^m x_i = x}} \sum_{i=1}^m f_i(x_i) \quad (3.6)$$

The next result establishes a connection between the support function of the intersection of two convex sets and the infimal convolution of the support functions of the sets taken by themselves. The proof translates the geometric concept of convex separation to the world of convex functions.

Theorem 3.3. *Let C_1 and C_2 be two non-empty convex sets in \mathbb{R}^n with $\text{ri}(C_1) \cap \text{ri}(C_2) \neq \emptyset$. Then the support function of the intersection $C_1 \cap C_2$ is represented as*

$$(\sigma_{C_1 \cap C_2})(x^*) = (\sigma_{C_1} \square \sigma_{C_2})(x^*) \quad \text{for all } x^* \in \mathbb{R}^n. \quad (3.7)$$

Furthermore, for any $x^ \in \text{dom}(\sigma_{C_1 \cap C_2})$ there exist dual elements $x_1^*, x_2^* \in \mathbb{R}^n$ such that $x^* = x_1^* + x_2^*$. and*

$$(\sigma_{C_1 \cap C_2})(x^*) = \sigma_{C_1}(x_1^*) + \sigma_{C_2}(x_2^*). \quad (3.8)$$

Proof. [MMN22, Theorem 4.23]

Read beginning of proof in reference (p.266).

We want to use results on convex separation. To make the geometric property of convex separation fruitful to our purpose we consider two special sets. We

3.1 A Convex Analysis Primer

will verify that these sets meet the requirements for convex separation, i.e., that they are convex and the intersection of their relative interiors is empty. Then a simple calculation will yield \geq . To this end, consider the sets

$$\Theta_1 := C_1 \times [0, \infty) \quad \text{and} \quad \Theta_2 := \{(x, \lambda) \in \mathbb{R}^n : x \in C_2 \text{ and } \lambda \leq \langle x^*, x \rangle - \alpha\}. \quad (3.9)$$

Simplify proof with properties of relative interiors.

Clearly, Θ_1 is convex by the convexity of C_1 . To see that Θ_2 is convex consider the affine function $\varphi : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}$, $(x, \lambda) \mapsto \alpha - \langle x^*, x \rangle - \lambda$. From the definitions of φ and Θ_2 we get the identity

$$\Theta_2 = (C_2 \times \mathbb{R}) \cap \varphi^{-1}(-\infty, 0].$$

Thus, by the convexity of the sets C_2 and $\varphi^{-1}(-\infty, 0]$ it follows the convexity of Θ_2 . Next we show that the relative interiors of Θ_1 and Θ_2 do not intersect, i.e., $\text{ri } \Theta_1 \cap \text{ri } \Theta_2 = \emptyset$. First note that

$$\text{ri}(\Theta_1) = \text{ri}(C_1) \times \text{ri}([0, \infty)) \subseteq \text{ri}(C_1) \times (0, \infty). \quad (3.10)$$

Indeed, if $0 \in \text{ri}([0, \infty))$ then there exists $t > 0$ such that $-tx \geq 0$ for some $x > 0$. A contradiction. Furthermore

$$\text{ri}(\Theta_2) \subseteq \{(x, \lambda) \in \mathbb{R}^n : x \in \text{ri}(C_2) \text{ and } \lambda < \langle x^*, x \rangle - \alpha\}. \quad (3.11)$$

To see this, assume there is $(x, \lambda) \in \text{ri}(\Theta_2)$ with $\lambda = \langle x^*, x \rangle - \alpha$. Then for some $(y, \mu) \in \Theta_2$ with $\mu < \langle x^*, y \rangle - \alpha$ there exists $t > 0$ such that $(x, \lambda) + t((x, \lambda) - (y, \mu)) \in \Theta_2$. It follows

$$0 \leq (1+t)(\langle x^*, x \rangle - \alpha - \lambda) + t(\mu - \langle x^*, y \rangle + \alpha) < 0, \quad (3.12)$$

a contradiction. The first inequality is due to $(x, \lambda) + t((x, \lambda) - (y, \mu)) \in \Theta_2$ and the second inequality due to $\mu < \langle x^*, y \rangle - \alpha$ and $\lambda = \langle x^*, x \rangle - \alpha$. But then $\text{ri}(\Theta_1) \cap \text{ri}(\Theta_2) = \emptyset$. Indeed, suppose that there exists $(x, \lambda) \in \text{ri}(\Theta_1) \cap \text{ri}(\Theta_2)$. Then it holds $\langle x^*, x \rangle - \alpha \leq 0$ and $\lambda > 0$ since $x \in \text{ri}(C_1) \cap \text{ri}(C_2) \subseteq C_1 \cap C_2$. On the other hand

$$0 < \lambda < \langle x^*, x \rangle - \alpha \leq 0, \quad (3.13)$$

a contradiction.

Finish proof.

Takeaways This primer is somewhat confusing.

Add more meaning.

3.2 Conjugate Calculus and Fenchel-Rockafellar Theorem

The goal of this section is to establish the tools to calculate convex conjugates. We prove the conjugate sum and chain rule. After some examples, we will derive the Fenchel-Rockafellar Theorem.

Definition 3.5. (Convex conjugate) *Given a function $f : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$, the **convex conjugate** $f^* : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ of f is defined as*

$$f^*(x^*) := \sup_{x \in \mathbb{R}^n} (x^*)^T x - f(x) \quad (3.14)$$

Add comment on nomenclature. What is Legendre transformation in this context?

Note that f in Definition 3.5 does not have to be convex. On the other hand, the convex conjugate is always convex:

Proposition 3.2. *Let $f : \mathbb{R}^n \rightarrow (-\infty, \infty]$ be a proper function. Then its convex conjugate $f^* : \mathbb{R}^n \rightarrow (-\infty, \infty]$ is convex.*

Proof. [MMN22, Proposition 4.2]

Give proof Mordukhovich2022 p.256

□

Lemma 3.1. *For any proper function $f : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ we have*

$$f^*(x^*) = \sigma_{\text{epi}(f)}(x^*, -1) \quad \text{for } x^* \in \mathbb{R}^n. \quad (3.15)$$

Proof. Let $x^* \in \mathbb{R}^n$ and $(x, \lambda) \in \text{epi}(f)$. Then $x \in \text{dom}(f)$ and $f(x) \leq \lambda$. Thus

$$\langle x^*, x \rangle - f(x) \geq \langle x^*, x \rangle - \lambda \quad \text{for all } (x, \lambda) \in \text{epi}(f). \quad (3.16)$$

On the other hand $(x, f(x)) \in \text{epi}(f)$ for all $x \in \text{dom}(f)$. It follows

$$\langle x^*, x \rangle - f(x) \leq \sup_{(x, \lambda) \in \text{epi}(f)} \langle x^*, x \rangle - \lambda \quad \text{for all } x \in \text{dom}(f). \quad (3.17)$$

3.2 Conjugate Calculus and Fenchel-Rockafellar Theorem

Taking the supremum in the last two displays yields

$$f^*(x^*) = \sup_{x \in \text{dom}(f)} \langle x^*, x \rangle - f(x) = \sup_{(x, \lambda) \in \text{epi}(f)} \langle x^*, x \rangle - \lambda \quad (3.18)$$

$$= \sup_{(x, \lambda) \in \text{epi}(f)} \langle (x^*, -1), (x, \lambda) \rangle = \sigma_{\text{epi}(f)}(x^*, -1). \quad (3.19)$$

□

Theorem 3.4. (Conjugate Chain Rule) *Let $A : \mathbb{R}^m \rightarrow \mathbb{R}^n$ be a linear map (matrix) and $g : \mathbb{R}^n \rightarrow (-\infty, \infty]$ a proper convex function. If $\text{Im}(A) \cap \text{ri}(\text{dom}(g)) \neq \emptyset$ it follows*

$$(g \circ A)^*(x^*) = \inf_{y^* \in (A^*)^{-1}(x^*)} g^*(y^*). \quad (3.20)$$

Furthermore, for any $x^* \in \text{dom}(g \circ A)^*$ there exists $y^* \in (A^*)^{-1}(x^*)$ such that $(g \circ A)^*(x^*) = g^*(y^*)$.

Proof. [MMN22, Proposition 4.28]

Provide proof. Mordukhovich2022 p.270

□

Theorem 3.5. *Let $f, g : \mathbb{R}^n \rightarrow (-\infty, \infty]$ be proper convex functions and $\text{ri}(\text{dom}(f)) \cap \text{ri}(\text{dom}(g)) \neq \emptyset$. Then we have the conjugate sum rule*

$$(f + g)^*(x^*) = (f^* \square g^*)(x^*) \quad (3.21)$$

for all $x^* \in \mathbb{R}^n$. Moreover, the infimum in $(f^* \square g^*)(x^*)$ is attained, i.e., for any $x^* \in \text{dom}(f + g)^*$ there exists vectors x_1^*, x_2^* for which

$$(f + g)^*(x^*) = f^*(x_1^*) + g^*(x_2^*), \quad x^* = x_1^* + x_2^*. \quad (3.22)$$

Proof. Let $x^* \in \mathbb{R}^n$ and fix $x_1^*, x_2^* \in \mathbb{R}^n$ such that $x^* = x_1^* + x_2^*$. We get

$$\begin{aligned} f^*(x_1^*) + g^*(x_2^*) &= \sup_{x \in \mathbb{R}^n} \langle x_1^*, x \rangle - f(x) + \sup_{x \in \mathbb{R}^n} \langle x_2^*, x \rangle - g(x) \\ &\geq \sup_{x \in \mathbb{R}^n} \langle x_1^*, x \rangle - f(x) + \langle x_2^*, x \rangle - g(x) = \sup_{x \in \mathbb{R}^n} \langle x_1^* + x_2^*, x \rangle - (f(x) + g(x)) \\ &= \sup_{x \in \mathbb{R}^n} \langle x^*, x \rangle - (f + g)(x) = (f + g)^*(x^*) \end{aligned}$$

Taking the infimum over $x_1^*, x_2^* \in \mathbb{R}^n$ in the above display gives $(f^* \square g^*)(x^*) \geq (f + g)^*(x^*)$. Let us prove now \leq under the condition $\text{ri}(\text{dom}(f)) \cap \text{ri}(\text{dom}(g)) \neq \emptyset$

3 Convex Analysis

\emptyset . The only case we need to consider is $(f + g)^*(x^*) < \infty$. Define two convex sets by

$$\Omega_1 := \{(x, \alpha, \beta) \in \mathbb{R}^{n+2} : \alpha \geq f(x)\} = \text{epi}(f) \times \mathbb{R}, \quad (3.23)$$

$$\Omega_2 := \{(x, \alpha, \beta) \in \mathbb{R}^{n+2} : \beta \geq g(x)\}. \quad (3.24)$$

Similar to Lemma we get the representation

$$(f + g)^*(x^*) = \sigma_{\Omega_1 \cap \Omega_2}(x^*, -1, -1). \quad (3.25)$$

Indeed, the only thing we need to verify is $\text{dom}(f) \cap \text{dom}(g) = \text{dom}(f + g)$. The inclusion \subseteq is clear. Assume towards a contradiction that $(f + g)(x) < \infty$ and $f(x) = \infty$. Since $g(x) > -\infty$ it holds

$$\infty = \infty + g(x) = f(x) + g(x) = (f + g)(x) < \infty. \quad (3.26)$$

This is a contradiction. The same holds for f and g reversed. It follows the inclusion \supseteq and equality. By the support function intersection rule there exist triples

$$(x_1^*, -\alpha_1, -\beta_1), (x_2^*, -\alpha_2, -\beta_2) \in \mathbb{R}^{n+2} \quad \text{such that} \quad (x^*, -1, -1) = (x_1^* + x_2^*, -(\alpha_1 + \alpha_2), -(\beta_1 + \beta_2)) \quad (3.27)$$

and

$$(f + g)^*(x^*) = \sigma_{\Omega_1 \cap \Omega_2}(x^*, -1, -1) = \sigma_{\Omega_1}(x_1^*, -\alpha_1, -\beta_1) + \sigma_{\Omega_2}(x_2^*, -\alpha_2, -\beta_2). \quad (3.28)$$

Next we show $\beta_1 = \alpha_2 = 0$. Suppose towards a contradiction that $\beta_1 \neq 0$. We fix $(\bar{x}, \bar{\alpha}) \in \text{epi}(f)$. Then

$$\sigma_{\Omega_1}(x_1^*, -\alpha_1, -\beta_1) = \sup_{(x, \alpha, \beta) \in \text{epi}(f) \times \mathbb{R}} \langle x^*, x \rangle - \alpha\alpha_1 - \beta\beta_1 \geq \sup_{\beta \in \mathbb{R}} \langle x^*, \bar{x} \rangle - \bar{\alpha}\alpha_1 - \beta\beta_1 = \infty. \quad (3.29)$$

This contradicts $(f + g)^*(x^*) < \infty$. In a similar fashion we can derive a contradiction for $\alpha_2 \neq 0$. Employing Lemma and taking into account the structures of the sets Ω_1 and Ω_2 this implies

$$(f + g)^*(x^*) = \sigma_{\Omega_1 \cap \Omega_2}(x^*, -1, -1) = \sigma_{\Omega_1}(x_1^*, -1, 0) + \sigma_{\Omega_2}(x_2^*, 0, -1) \quad (3.30)$$

$$= \sigma_{\text{epi}(f)}(x_1^*, -1) + \sigma_{\text{epi}(g)}(x_2^*, -1) = f^*(x_1^*) + g^*(x_2^*) \geq (f^* \square g^*)(x^*). \quad (3.31)$$

This finishes the proof. \square

3.2 Conjugate Calculus and Fenchel-Rockafellar Theorem

Include lemma on convex conjugates of indicator functions. This should be straightforward.

Write example on convex conjugates of $F(w) = \sum_{i=1}^n f(w_i)$. See notes.

Find right moment to introduce nomenclature for optimization problem. See also end of Tseng Bertsekas chapter.

Given proper convex functions $f, g : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ and a matrix $A \in \mathbb{R}^{n \times n}$, we define the primal minimization problem as follows:

Problem 3.1. (Primal) *Given proper convex functions $f : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$, $g : \mathbb{R}^m \rightarrow \overline{\mathbb{R}}$ and a matrix $A \in \mathbb{R}^{m \times n}$ we define the **primal optimization problem** to be*

$$\underset{x \in \mathbb{R}^n}{\text{minimize}} \quad f(x) + g(Ax)$$

Remark 3.1. *Problem 3.1 appears in the unconstrained form. We can impose constraints by controlling for the domains of f and g . To incorporate linear constraints $Ax \leq 0$ or more general constraints $x \in \Omega$, where Ω is a convex set, we can choose*

$$g(x) = \delta_{\Omega}(x) := \begin{cases} 0 & \text{if } x \in \Omega \\ \infty & \text{if } x \notin \Omega \end{cases} \quad (3.32)$$

where $x \notin \Omega$ leads to $f(x) + g(x) = \infty$ and the optimization problem (if feasible) will exclude x from the solutions. \diamond

Problem 3.2. (Dual) *Consider the same setting as in Problem 3.1. Using the convex conjugates of f, g and the transpose of A we define the **dual problem** of Problem 3.1 to be*

$$\underset{y^* \in \mathbb{R}^m}{\text{maximize}} \quad -f^*(A^\top y^*) - g^*(y^*).$$

Proposition 3.3. *Consider the optimization problem 3.1 and its dual 3.2, where the functions f and g are not assumed to be convex. Define the **optimal values** of these problems by*

$$\hat{p} := \inf_{x \in \mathbb{R}^n} f(x) + g(Ax) \quad \text{and} \quad \hat{d} := \sup_{y \in \mathbb{R}^m} -f^*(A^\top y) - g^*(y).$$

Then we have the relationship $\hat{d} \leq \hat{p}$.

3 Convex Analysis

Proof. It holds

$$\begin{aligned}
-f^*(A^\top y^*) - g^*(y^*) &= -\sup_{x \in \mathbb{R}^n} \langle A^\top y^*, x \rangle - f(x) - \sup_{y \in \mathbb{R}^m} \langle -y^*, y \rangle - g(y) \\
&= \inf_{x \in \mathbb{R}^n} f(x) - \langle y^*, Ax \rangle + \inf_{y \in \mathbb{R}^m} g(y) + \langle y^*, y \rangle \\
&\leq \inf_{x \in \mathbb{R}^n} f(x) - \langle y^*, Ax \rangle + \inf_{x \in \mathbb{R}^n} g(Ax) + \langle y^*, Ax \rangle \\
&\leq \inf_{x \in \mathbb{R}^n} f(x) - \langle y^*, Ax \rangle + g(Ax) + \langle y^*, Ax \rangle \\
&= \inf_{x \in \mathbb{R}^n} f(x) + g(Ax) = \hat{p}
\end{aligned}$$

The first equality is due to the definition of convex conjugates, the second equality due to $\langle A^\top y, x \rangle = \langle y, Ax \rangle$ and $\inf \{-B\} = -\sup \{B\}$ for all $B \subseteq \overline{\mathbb{R}}$ and the first inequality due to $\text{Im}(A) \subseteq \mathbb{R}^m$. Taking the supremum with respect to all $y^* \in \mathbb{R}^m$ yields the result. \square

Provide proof (Mordukhovich2022 p.293)

Theorem 3.6. Let $f, g : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ be proper convex functions and $0 \in \text{ri}(\text{dom}(g) - A(\text{dom}(f)))$. Then the optimal values of (3.1) and (3.2) are equal, i.e.

$$\inf_{x \in \mathbb{R}^n} \{f(x) + g(Ax)\} = \sup_{y \in \mathbb{R}^n} \{-f^*(A^\top y) - g^*(-y)\}. \quad (3.33)$$

Proof. [MMN22, Theorem 4.63] \square

Insert lemma in chapter 1.

Lemma 3.2. Let $f : \mathbb{R}^n \rightarrow (-\infty, \infty]$ be convex. Then for all $y \in \mathbb{R}^n$ and $C > 0$

$$\inf_{\|\Delta\|=C} f(y + \Delta) - f(y) \geq 0 \implies \exists y^* \in \mathbb{R}^n : y^* \text{ is global minimum of } f \text{ and } \|y^* - y\| \leq C. \quad (3.34)$$

Proof. Since $\mathcal{C} := \{\|\Delta\| \leq C\}$ is convex f has a local minimum in $y + \mathcal{C} := \{y + \Delta \mid \|\Delta\| \leq C\}$. Suppose towards a contradiction that $y^* \in y + \mathcal{C}$ is a local minimum, but not a global minimum and the left-hand side of (3.34) is true. Then it holds

$$f(x) < f(y^*) \quad \text{for some } x \in \mathbb{R}^n \setminus y + \mathcal{C}. \quad (3.35)$$

Furthermore since $y + \mathcal{C}$ is compact and contains y^* , the line segment $\mathcal{L}[y^*, x]$ contains a point on the boundary of $y + \mathcal{C}$, i.e.

$$\theta x + (1 - \theta)y^* = y + \Delta_x \quad \text{for some } \theta \in (0, 1) \text{ and } \Delta_x \text{ with } \|\Delta_x\| = C. \quad (3.36)$$

It follows

$$\begin{aligned} f(y^*) &\leq f(y) \leq f(y + \Delta_x) = f(\theta x + (1 - \theta)y^*) \\ &\leq \theta f(x) + (1 - \theta)f(y^*) < f(y^*), \end{aligned} \tag{3.37}$$

which is a contradiction. Thus every local minimum of f in $y + \mathcal{C}$ is also a global minimum. The first inequality is due to y^* being a local minimum of f in $y + \mathcal{C}$, the second inequality is due to the left-hand side of (3.34) being true, the equality is due to (3.36), the third inequality is due to the convexity of f and the strict inequality is due to (3.35). \square

Takeaways Almost there

Add more meaning.

3.3 Tseng Bertsekas

We present the relevant parts of the paper [BT03].

Consider the following optimization problem

$$\underset{x \in \mathbb{R}^m}{\text{minimize}} \quad f(x)$$

subject to the constraints

$$\mathbf{A}x \geq b, \tag{3.38}$$

Where $f : \mathbb{R}^m \rightarrow \overline{\mathbb{R}}$, \mathbf{A} is a given $n \times m$ matrix, and b is a vector in \mathbb{R}^n .

Generalize also to take equality constraints. Write in unconstrained form to derive dual.

Assumption 3.1. Assume that the map $f : \mathbb{R}^m \rightarrow \overline{\mathbb{R}}$ has the following properties.

- (i) f is strictly convex.
- (ii) f is lower-semicontinuous and continuous $\text{dom}(f)$.
- (iii) The convex conjugate f^* of f is finite.

3 Convex Analysis

The dual optimization problem associated with (P) is

$$\underset{p \in \mathbb{R}^n}{\text{maximize}} \quad q(p)$$

subject to the constraints

$$p \geq 0, \tag{3.39}$$

where $q : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ is the concave function given by

$$q(p) := \min_{x \in \mathbb{R}^m} f(x) + \langle p, b - \mathbf{A}x \rangle = \langle p, b \rangle - f^*(\mathbf{A}^\top p). \tag{3.40}$$

The dual problem (D) is a concave program with simple nonnegativity constraints. Furthermore, strong duality holds for (P) and (D) , i.e., the optimal value of (P) equals the optimal value of (D) .

Since f^* is real-valued and f is strictly convex, f^* and q are continuously differentiable.

Theorem 3.7. [Roc70, Theorem 26.3] *A closed proper convex function is (essentially) strictly convex if and only if its conjugate is essentially smooth.*

Read and understand proof (p.270)

We will denote the gradient of q at p by $d(p)$ and its i th coordinate by $d_i(p)$. Since q is continuously differentiable, $d_i(p)$ is continuous, and since q is concave, $d_i(p)$ as nonincreasing in p_i .

By differentiating and by using the chain rule, we obtain the dual cost gradient

$$d(p) = b - \mathbf{A}x, \quad \text{where} \quad x := \nabla f^*(\mathbf{A}^\top p) = \operatorname{argsup}_{\xi \in \mathbb{R}^m} \langle p, \mathbf{A}\xi \rangle - f(\xi). \tag{3.41}$$

The last equality follows from Danskin's Theorem and [Roc70, Theorem 23.5]

Read and understand proof (p.80)

Proposition 3.4. (Danskin's Theorem [BT03, page 649]) *Let $Z \subseteq \mathbb{R}^m$ be a non-empty set, and let $\phi : \mathbb{R}^n \times Z \rightarrow \mathbb{R}$ be a continuous function such that $\phi(\cdot, z) : \mathbb{R}^n \rightarrow \mathbb{R}$, viewed as a function of its first argument, is convex for each $z \in Z$. Then the function*

$$f : \mathbb{R}^n \rightarrow \mathbb{R}, \quad x \mapsto \sup_{z \in Z} \phi(x, z) \tag{3.42}$$

is convex and has directional derivative given by

$$f'(x; y) = \sup_{z \in Z(x)} \phi'(x, z; y), \quad (3.43)$$

where $\phi'(x, z; y)$ is the directional derivative of the function $\phi(\cdot, z)$ at x in the direction y , and

$$Z(x) := \left\{ \bar{z} \in \mathbb{R}^m : \phi(x, \bar{z}) = \sup_{z \in Z} \phi(x, z) \right\}. \quad (3.44)$$

In particular, if $Z(x)$ consists of a unique point \bar{z} and $\phi(\cdot, \bar{z})$ is differentiable at x , and $\nabla f(x) = \nabla_x \phi(x, \bar{z})$, where $\nabla_x \phi(x, \bar{z})$ is the vector with coordinates $(\partial \phi / \partial x_i)(x, \bar{z})$

Note that x is the unique vector satisfying

$$\mathbf{A}p \in \partial f(x). \quad (3.45)$$

From the optimality conditions for (D) it follows that a dual vector is an optimal solution of (D) if and only if

$$p = [p + d(p)]^+, \quad (3.46)$$

where $[\cdot]^+$ is the projection onto the positive orthant, i.e., $[y]^+ = [0 \vee y_1, \dots, 0 \vee y_n]^T$.

Provide details. See notes.

Given an optimal dual solution p , we may obtain an optimal primal solution from the equation $x = \nabla f^*(\mathbf{A}^\top p)$. To see this, note that

$$\mathbf{A}x \geq b \quad \text{and} \quad p_i = 0 \quad \text{for all } i \text{ such that } \sum_{j=1}^m a_{ij}x_j > b_i. \quad (3.47)$$

We can show that p and x satisfy the KKT conditions and thus x is an optimal solution to (P) .

n

Definition 3.6. [Roc70, §28] By an **ordinary convex program** (P) we mean an optimization problem of the following form

$$\underset{x \in C}{\text{minimize}} \quad f_0(x)$$

subject to the constraints

$$f_1(x) \leq 0, \dots, f_r(x) \leq 0, \quad f_{r+1}(x) = 0, \dots, f_m(x) = 0, \quad (3.48)$$

where $C \subseteq \mathbb{R}^n$ is a non-empty convex set, f_i is a finite convex function on C for $i \in \{1, \dots, r\}$ and f_i is an affine function on C for $i \in \{r+1, \dots, m\}$.

3 Convex Analysis

Definition 3.7. We define $[\lambda_1, \dots, \lambda_m] \in \mathbb{R}^m$ to be a **Karush-Kuhn-Tucker (KKT) vector** for (P) , if

- (i) $\lambda_i \geq 0$ for all $i \in \{1, \dots, r\}$.
- (ii) The infimum of the proper convex function $f_0 + \sum_{i=1}^m \lambda_i f_i$ is finite and equal to the optimal value in (P) .

Theorem 3.8. (Karush-Kuhn-Tucker conditions) Let (P) be an ordinary convex program, $\bar{\alpha} \in \mathbb{R}^m$, and $\bar{z} \in \mathbb{R}^n$. Then $\bar{\alpha}$ is a KKT vector for (P) and \bar{z} is an optimal solution to (P) if and only if \bar{z} and the components α_i of $\bar{\alpha}$ satisfy the following conditions.

- (i) $\alpha_i \geq 0$, $f_i(\bar{z}) \leq 0$, and $\alpha_i f_i(\bar{z}) = 0$ for all $i \in \{1, \dots, r\}$.
- (ii) $f_i(\bar{z}) = 0$ for $i \in \{r+1, \dots, m\}$.
- (iii) $0_n \in [\partial f_0(\bar{z}) + \sum_{\alpha_i \neq 0} \alpha_i \partial f_i(\bar{z})]$.

Proof. [Roc70, Theorem 28.3] □

Takeaways For strictly convex functions we can derive duality in terms of the optimal solutions.

4 Random Matrix Inequalities

In our application we want to bound moments of vector-valued random variables. For this we choose the theory of random matrix inequalities which lately received a lot of attention. In particular an approach via the method of exchangeable pairs [MJC⁺14] has been fruitful in simplifying the proofs of long standing results such as the matrix Khintchin inequality. We base our exposition on [MJC⁺14]. A lot will be exact copy of this paper, so no originality is claimed. Where it seemed fit, we conducted some calculations in more detail than presented in the paper.

We will first introduce the method of exchangeable pairs and derive auxiliary theorems to establish the matrix Khintchin inequality. Then we will derive inequalities for moments of matrices, first for psd matrices and then via the Hermitian dilataition for general rectangular matrices. In a last step we will introduce the notion of intrinsic dimension to improve the bounds.

4.1 A Matrix Analysis Primer

The **trace** of a square matrix, denoted by tr , is the sum of its diagonal entries, i.e. $\text{tr}(\mathbf{B}) = \sum_{j=1}^d b_{jj}$ for $\mathbf{B} \in \mathbb{M}_d$. The trace is unitarily invariant, i.e. $\text{tr}(\mathbf{B}) = \text{tr}(\mathbf{QBQ}^*)$ for all $\mathbf{B} \in \mathbb{M}_d$ for all unitary $\mathbf{Q} \in \mathbb{M}_d$. In particular, the existence of an eigenvalue value decomposition shows that the trace of a Hermitian matrix equals the sum of its eigenvalues. Let $f : I \rightarrow \mathbb{R}$ where $I \subseteq \mathbb{R}$ is an interval. Consider a matrix $\mathbf{A} \in \mathbb{H}_d$ whose eigenvalues are contained in I . We define the matrix $f(\mathbf{A}) \in \mathbb{H}_d$ using an eigenvalue decomposition of \mathbf{A} :

$$f(\mathbf{A}) = \mathbf{Q} \begin{bmatrix} f(\lambda_1) & & \\ & \ddots & \\ & & f(\lambda_d) \end{bmatrix} \mathbf{Q}^* \quad \text{where} \quad \mathbf{A} = \mathbf{Q} \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_d \end{bmatrix} \mathbf{Q}^* = \sum_{i=1}^d \lambda_i \mathbf{Q}_{\bullet i} \mathbf{Q}_{\bullet i}^*. \quad (4.1)$$

The definition of $f(\mathbf{A})$ does not depend on which eigenvalue decomposition we choose. Any matrix function that arises in this fashion is called a **standard matrix function**.

4 Random Matrix Inequalities

For each $p \geq 1$ the **Schatten p -norm** is defined as $\|\mathbf{B}\|_p := (\text{tr}(|\mathbf{B}|^p))^{1/p}$ for $\mathbf{B} \in \mathbb{M}_d$. In this setting, $|\mathbf{B}| := (\mathbf{B}^* \mathbf{B})^{1/2}$. The **spectral norm** of an Hermitian matrix \mathbf{A} is defined by the relation $\|\mathbf{A}\| := \lambda_{\max}(\mathbf{A}) \vee (-\lambda_{\min}(\mathbf{A}))$. For a general matrix \mathbf{B} , the spectral norm is defined to be the largest singular value: $\|\mathbf{B}\| := \sigma_1(\mathbf{B})$. The Schatten p -norm dominates the spectral norm for all $p \geq 1$.

Proposition 4.1. *Let $f, g : I \rightarrow \mathbb{R}$ be real-valued functions on an interval $I \subseteq \mathbb{R}$, and let $\mathbf{A} \in \mathbb{H}_d$ be a Hermitian matrix whose eigenvalues are contained in I .*

(i) *If λ is an eigenvalue of \mathbf{A} , then $f(\lambda)$ is an eigenvalue of $f(\mathbf{A})$.*

(ii) *$f(a) \leq g(a)$ for all $a \in I$ implies $f(\mathbf{A}) \preceq g(\mathbf{A})$.*

4.2 The Method of Exchangeable Pairs

We first define an exchangeable pair.

Definition 4.1. *Let Z and Z' random variables taking values in a Polish space \mathcal{Z} . We say that (Z, Z') is an **exchangeable pair** if it has the same distribution as (Z', Z) . In particular, Z and Z' must share the same distribution.*

The following approach originates in the work of Charles Stein [Ste72] on normal approximation for a sum of dependent random variable. We will explain how some central ideas of this theory extends to matrices.

We can obtain a lot of information about the fluctuation of a random matrix \mathbf{X} if we can construct a good exchangeable pair $(\mathbf{X}, \mathbf{X}')$. With this motivation in mind, let us introduce a special class of exchangeable pairs.

4.2 The Method of Exchangeable Pairs

Definition 4.2. Let (Z, Z') be an exchangeable pair of random variables taking values in a Polish space \mathcal{Z} , and let $\Psi : \mathcal{Z} \rightarrow \mathbb{H}_d$ be a measurable function. Define the random Hermitian matrices

$$\mathbf{X} := \Psi(Z) \quad \text{and} \quad \mathbf{X}' := \Psi(Z'). \quad (4.2)$$

We say that $(\mathbf{X}, \mathbf{X}')$ is a **matrix Stein pair** if there is a constant $\alpha \in (0, 1]$ for which

$$\mathbf{E}[\mathbf{X} - \mathbf{X}' | Z] = \alpha \mathbf{X} \quad \text{almost surely.} \quad (4.3)$$

The constant α is called the **scale factor** of the pair. We always assume $\mathbf{E}[\|\mathbf{X}\|^2] < \infty$.

A matrix Stein pair $(\mathbf{X}, \mathbf{X}')$ has several useful properties. First, $(\mathbf{X}, \mathbf{X}')$ always forms an exchangeable pair. Second, it must be the case that $\mathbf{E}[\mathbf{X}] = \mathbf{0}$. Indeed,

$$\mathbf{E}[\mathbf{X}] = \frac{1}{\alpha} \mathbf{E}[\mathbf{E}[\mathbf{X} - \mathbf{X}' | Z]] = \frac{1}{\alpha} \mathbf{E}[\mathbf{X} - \mathbf{X}'] = \mathbf{0}.$$

A well-chosen matrix Stein pair $(\mathbf{X}, \mathbf{X}')$ provides a surprisingly powerful tool for studying the random matrix \mathbf{X} . The technique depends on a fundamental technical lemma.

Lemma 4.1. Suppose that $(\mathbf{X}, \mathbf{X}')$ is a matrix Stein pair with scale factor α . Let $\mathbf{F} : \mathbb{H}_d \rightarrow \mathbb{H}_d$ be a measurable function that satisfies the regularity condition $\mathbf{E}[\|(\mathbf{X} - \mathbf{X}')\mathbf{F}(\mathbf{X})\|] < \infty$. Then

$$\mathbf{E}[\mathbf{X} \cdot \mathbf{F}(\mathbf{X})] = \frac{1}{2\alpha} \mathbf{E}[(\mathbf{X} - \mathbf{X}')(\mathbf{F}(\mathbf{X}) - \mathbf{F}(\mathbf{X}'))]. \quad (4.4)$$

In short, the randomness in the Stein pair furnishes an alternative expression for the expected product of \mathbf{X} and a function \mathbf{F} . It allows us to estimate the expectation using the smoothness properties of the function \mathbf{F} and the discrepancy between \mathbf{X} and \mathbf{X}' .

Proof. [MJC⁺ 14, Lemma 2.4] Suppose that $(\mathbf{X}, \mathbf{X}')$ constructed from an auxiliary exchangeable pair (Z, Z') . The defining property implies

$$\alpha \cdot \mathbf{E}[\mathbf{X} \cdot \mathbf{F}(\mathbf{X})] = \mathbf{E}[\mathbf{E}[\mathbf{X} - \mathbf{X}' | Z] \cdot \mathbf{F}(\mathbf{X})] = \mathbf{E}[(\mathbf{X} - \mathbf{X}')\mathbf{F}(\mathbf{X})] \quad (4.5)$$

□

4 Random Matrix Inequalities

To each matrix Stein pair $(\mathbf{X}, \mathbf{X}')$, we may associate a random matrix called the conditional variance of \mathbf{X} . The purpose of this section is to argue that the spectral norm of \mathbf{X} is unlikely to be large, when the conditional variance is small.

Definition 4.3. Suppose that $(\mathbf{X}, \mathbf{X}')$, is a matrix Stein pair, constructed from an auxiliary exchangeable pair (Z, Z') . The **conditional variance** is the random matrix

$$\Delta_{\mathbf{X}} := \Delta_{\mathbf{X}}(Z) := \frac{1}{2\alpha} \mathbf{E}[(\mathbf{X} - \mathbf{X}')^2 | Z], \quad (4.6)$$

where α is the scale factor of the pair. We may take any version of the conditional expectation in this definition.

The conditional variance $\Delta_{\mathbf{X}}$ can be regarded as a stochastic estimate for the variance of the random matrix \mathbf{X} . To see this, assume the second moment of \mathbf{X} exists. Then it follows from Lemma with $\mathbf{F}(\mathbf{X}) = \mathbf{X}$

$$\mathbf{E}[\Delta_{\mathbf{X}}] = \mathbf{E}[\mathbf{X}^2]. \quad (4.7)$$

To verify the regularity condition, note that

$$\mathbf{E}[\|(\mathbf{X} - \mathbf{X}')\mathbf{X}\|] \leq \mathbf{E}[\|\mathbf{X}\|^2] + \mathbf{E}[\|\mathbf{X}\| \cdot \|\mathbf{X}'\|] \leq 2\mathbf{E}[\|\mathbf{X}\|^2] < \infty. \quad (4.8)$$

Example 4.1. [MJC⁺ 14, Example 2.4]

4.3 Matrix Khintchin Inequality and Applications

The goal of this section is to derive the matrix Khintchin inequality and show some important applications. For this we need an auxiliary theorem which is an extension of the *Burkholder-Davis-Gundy (BDG) inequality* from classical martingale theory [Bur73]. We prepare for the proof of this theorem by assembling some analytic tools.

Proposition 4.2. (Generalized Klein inequality) *Let u_1, \dots, u_n and v_1, \dots, v_n be real-valued functions on an interval I of the real line. Suppose*

$$\sum_{k=1}^n u_k(a)v_k(b) \geq 0 \quad \text{for all } a, b \in I. \quad (4.9)$$

Then

$$\overline{\text{tr}} \left(\sum_{k=1}^n u_k(\mathbf{A})v_k(\mathbf{B}) \right) \geq 0 \quad \text{for all } \mathbf{A}, \mathbf{B} \in \mathbb{H}_d(I). \quad (4.10)$$

Proof. [Pet94, Proposition 3] Let $\mathbf{A} = \sum_{i=1}^d \lambda_i \mathbf{P}_{\bullet i} \mathbf{P}_{\bullet i}^*$ and $\mathbf{B} = \sum_{j=1}^d \mu_j \mathbf{Q}_{\bullet j} \mathbf{Q}_{\bullet j}^*$ be the orthonormal decompositions of \mathbf{A} and \mathbf{B} . Then

$$\overline{\text{tr}} \left(\sum_{k=1}^n u_k(\mathbf{A})v_k(\mathbf{B}) \right) = \sum_{k=1}^n \sum_{i,j=1}^d \overline{\text{tr}} (u_k(\lambda_i) \mathbf{P}_{\bullet i} \mathbf{P}_{\bullet i}^* v_k(\mu_j) \mathbf{Q}_{\bullet j} \mathbf{Q}_{\bullet j}^*) \quad (4.11)$$

$$= \sum_{i,j=1}^d \overline{\text{tr}} (\mathbf{P}_{\bullet i} \mathbf{P}_{\bullet i}^* \mathbf{Q}_{\bullet j} \mathbf{Q}_{\bullet j}^*) \sum_{k=1}^n u_k(\lambda_i) v_k(\mu_j) \geq 0 \quad (4.12)$$

by the hypothesis. To see that $\overline{\text{tr}} (\mathbf{P}_{\bullet i} \mathbf{P}_{\bullet i}^* \mathbf{Q}_{\bullet j} \mathbf{Q}_{\bullet j}^*)$ is non-negative for all $i, j \in \{1, \dots, d\}$, we apply a well known extension of von Neumann's trace inequality [Ruh70, Lemma 1], namely

$$\text{tr}(\mathbf{P}\mathbf{Q}) \geq \sum_{i=1}^d p_i q_{d-i+1} \geq 0 \quad \text{for all } \mathbf{P}, \mathbf{Q} \in \mathbb{H}_d([0, \infty)), \quad (4.13)$$

where the eigenvalues $p_1 \geq \dots \geq p_d$ and $q_1 \geq \dots \geq q_d$ are sorted decreasingly. \square

Lemma 4.2. (Mean value trace inequality) *Let I be an interval of the real line. Suppose that $g : I \rightarrow \mathbb{R}$ is a weakly increasing function and that $h : I \rightarrow \mathbb{R}$ is a*

4 Random Matrix Inequalities

function whose derivative h' is convex. Then for all matrices $\mathbf{A}, \mathbf{B} \in \mathbb{H}_d(I)$ it holds

$$\overline{\text{tr}}[(g(\mathbf{A}) - g(\mathbf{B})) \cdot (h(\mathbf{A}) - h(\mathbf{B}))] \leq \frac{1}{2} \overline{\text{tr}}[(g(\mathbf{A}) - g(\mathbf{B})) \cdot (\mathbf{A} - \mathbf{B}) \cdot (h'(\mathbf{A}) + h'(\mathbf{B}))]. \quad (4.14)$$

When h' is concave, the inequality is reversed. The same result holds for the standard trace.

Proof. [MJC⁺ 14, Lemma 3.4] Fix $a, b \in I$. Since g is weakly increasing, $(g(a) - g(b)) \cdot (a - b) \geq 0$. The fundamental theorem of calculus and the convexity of h' yield the estimate

$$(g(a) - g(b)) \cdot (h(a) - h(b)) = (g(a) - g(b)) \cdot (a - b) \int_0^1 h'(\tau a + (1 - \tau)b) d\tau \quad (4.15)$$

$$\leq (g(a) - g(b)) \cdot (a - b) \int_0^1 [\tau h'(a) + (1 - \tau)h'(b)] d\tau \quad (4.16)$$

$$= \frac{1}{2} [(g(a) - g(b)) \cdot (a - b) \cdot (h'(a) + h'(b))]. \quad (4.17)$$

The inequality is reversed, if h' is concave. To apply the Kleins inequality we expand the terms. The RHS is

$$\begin{aligned} & (g(a) - g(b)) \cdot (a - b) \cdot (h'(a) + h'(b)) \\ &= [g(a) \cdot a \cdot h'(a)] + [g(a) \cdot a] \cdot h'(b) - b \cdot [h'(a) \cdot g(a)] - [b \cdot h'(b)] \cdot g(a) \\ &+ [\text{the same as above with } a \text{ and } b \text{ reversed}] (a \rightleftharpoons b) \end{aligned} \quad (4.18)$$

Taking the trace yields

$$\begin{aligned} & \text{tr}[g(\mathbf{A}) \cdot \mathbf{A} \cdot (h'(\mathbf{A}) + h'(\mathbf{B}))] - \text{tr}[\mathbf{B} \cdot (h'(\mathbf{A}) + h'(\mathbf{B})) \cdot g(\mathbf{A})] + (\mathbf{A} \rightleftharpoons \mathbf{B}) \\ &= \text{tr}[g(\mathbf{A}) \cdot \mathbf{A} \cdot (h'(\mathbf{A}) + h'(\mathbf{B}))] - \text{tr}[g(\mathbf{A}) \cdot \mathbf{B} \cdot (h'(\mathbf{A}) + h'(\mathbf{B}))] + (\mathbf{A} \rightleftharpoons \mathbf{B}) \\ &= \text{tr}[g(\mathbf{A}) \cdot (\mathbf{A} - \mathbf{B}) \cdot (h'(\mathbf{A}) + h'(\mathbf{B}))] + (\mathbf{A} \rightleftharpoons \mathbf{B}) \\ &= \text{tr}[(g(\mathbf{A}) - g(\mathbf{B})) \cdot (\mathbf{A} - \mathbf{B}) \cdot (h'(\mathbf{A}) + h'(\mathbf{B}))]. \end{aligned} \quad (4.19)$$

On the LHS we have only products of two factors which commute under the trace operation. Thus we may use the same expression as in the scalar case

4.3 Matrix Khintchin Inequality and Applications

without further calculations. The result follows immediately from the Klein inequality. \square

Proposition 4.3. (Hölder inequality for trace) *Let p and q be Hölder conjugate indices. Then*

$$\text{tr}(\mathbf{BC}) \leq \|\mathbf{B}\|_p \|\mathbf{C}\|_q \quad \text{for all } \mathbf{B}, \mathbf{C} \in \mathbb{M}_d. \quad (4.20)$$

Proof. [Bha97, Corollary IV.2.6] \square

We are now ready to prove the auxiliary theorem.

Theorem 4.1. (Matrix BDG inequality) *Let $p = 1$ or $p \geq 3/2$. Suppose that $(\mathbf{X}, \mathbf{X}')$ is a matrix Stein pair where $\mathbf{E}[\|\mathbf{X}\|_{2p}^{2p}] < \infty$. Then*

$$\mathbf{E}[\|\mathbf{X}\|_{2p}^{2p}]^{1/(2p)} \leq \sqrt{2p-1} \mathbf{E}[\|\Delta_{\mathbf{X}}\|_p^p]^{1/(2p)}, \quad (4.21)$$

where $\Delta_{\mathbf{X}}$ is the conditional variance.

Proof. [MJC⁺14, §7.3] Suppose that $(\mathbf{X}, \mathbf{X}')$ is a matrix Stein pair with scale factor α . First, observe that the result for $p = 1$ already follows from $\mathbf{E}[\Delta_{\mathbf{X}}] = \mathbf{E}[\mathbf{X}^2]$. Therefore we may assume that $p \geq 3/2$. We introduce the notation for the quantity of interest,

$$E := \mathbf{E}[\|\mathbf{X}\|_{2p}^{2p}] = \mathbf{E}[\text{tr}(|\mathbf{X}|^{2p})]. \quad (4.22)$$

We rewrite the expression for E by peeling off a copy of $|\mathbf{X}|$. This yields

$$E = \mathbf{E}[\text{tr}(|\mathbf{X}| \cdot |\mathbf{X}|^{2p-1})] = \mathbf{E}[\text{tr}(\mathbf{X} \cdot \text{sgn}(\mathbf{X}) \cdot |\mathbf{X}|^{2p-1})]. \quad (4.23)$$

Apply the method of exchangeable pairs with $\mathbf{F}(\mathbf{X}) = \text{sgn}(\mathbf{X}) \cdot |\mathbf{X}|^{2p-1}$ to reach

$$E = \frac{1}{2\alpha} \mathbf{E}[\text{tr}((\mathbf{X} - \mathbf{X}') \cdot (\text{sgn}(\mathbf{X}) \cdot |\mathbf{X}|^{2p-1} - \text{sgn}(\mathbf{X}') \cdot |\mathbf{X}'|^{2p-1}))] \quad (4.24)$$

Apply method of exchangeable pairs, generalized Klein inequality, trace Hölder \square

Theorem 4.2. [MJC⁺14, Corollary 7.3] *Suppose that $p = 1$ or $p \geq 3/2$. Consider a finite sequence $(\mathbf{Y}_k)_{k \geq 1}$ of independent, random, Hermitian matrices and a deterministic sequence $(\mathbf{A}_k)_{k \geq 1}$ for which*

$$\mathbf{E}[\mathbf{Y}_k] = 0 \quad \text{and} \quad \mathbf{Y}_k^2 \preceq \mathbf{A}_k^2 \quad \text{almost surely for all } k \geq 1. \quad (4.25)$$

4 Random Matrix Inequalities

Then

$$\mathbf{E} \left[\left\| \sum_{k \geq 1} \mathbf{Y}_k \right\|_{2p}^{2p} \right]^{1/(2p)} \leq \sqrt{p - \frac{1}{2}} \left\| \left(\sum_{k \geq 1} (\mathbf{A}_k^2 + \mathbf{E}[\mathbf{Y}_k^2]) \right)^{1/2} \right\|_{2p}. \quad (4.26)$$

In particular, when $(\xi_k)_{k \geq 1}$ is an independent sequence of Rademacher random variables,

$$\mathbf{E} \left[\left\| \sum_{k \geq 1} \xi_k \mathbf{A}_k \right\|_{2p}^{2p} \right]^{1/(2p)} \leq \sqrt{2p - 1} \left\| \left(\sum_{k \geq 1} \mathbf{A}_k^2 \right)^{1/2} \right\|_{2p}. \quad (4.27)$$

Theorem 4.3. Assume $n \geq 3$

(i) Suppose that $p \geq 1$, and fix $r \geq p \vee 2 \log(n)$. Consider a finite sequence $(\mathbf{S}_k)_{k \geq 1}$ of independent, random, positive-semidefinite matrices with dimension $n \times n$. Then

$$\mathbf{E} \left[\left\| \sum_{k \geq 1} \mathbf{S}_k \right\|^p \right]^{1/p} \leq \left[\left\| \sum_{k \geq 1} \mathbf{E}[\mathbf{S}_k] \right\|^{1/2} + 2\sqrt{er} \mathbf{E}[\max_{k \geq 1} \|\mathbf{S}_k\|^p]^{1/(2p)} \right]^2. \quad (4.28)$$

(ii) Suppose that $p \geq 2$, and fix $r \geq p \vee 2 \log(n)$. Consider a finite sequence $(\mathbf{Y}_k)_{k \geq 1}$ of independent, symmetric, random, self-adjoint matrices with dimension $n \times n$. Then

$$\mathbf{E} \left[\left\| \sum_{k \geq 1} \mathbf{Y}_k \right\|^p \right]^{1/p} \leq \sqrt{er} \left\| \left(\sum_{k \geq 1} \mathbf{E}[\mathbf{Y}_k^2] \right)^{1/2} \right\| + 2er \mathbf{E}[\max_{k \geq 1} \|\mathbf{S}_k\|^p]^{1/p}. \quad (4.29)$$

Takeaways This is so amazing Nam dui ligula, fringilla a, euismod sodales, sollicitudin vel, wisi. Morbi auctor lorem non justo. Nam lacus libero, pretium at, lobortis vitae, ultricies et, tellus. Pellentesque cursus luctus mauris.

4.4 Generalized Inequalities by Hermitian Dilataition

Definition 4.4. (Hermitian Dilation) *The Hermitian dilation*

$$\mathfrak{H} : \mathbb{C}^{d_1 \times d_2} \rightarrow \mathbb{H}_{d_1 \times d_2}$$

is a map from a general matrix to an Hermitian matrix defined by

$$\mathfrak{H}(B) := \begin{bmatrix} 0 & B \\ B^* & 0 \end{bmatrix} \quad (4.30)$$

Theorem 4.4. (Matrix Rosenthal-Pinelis) *Let $\mathbf{A}_1, \dots, \mathbf{A}_n$ be independent, random matrices with dimension $d_1 \times d_2$. Introduce the random matrix*

$$\mathbf{S} := \sum_{k=1}^n \mathbf{A}_k.$$

Let $v(\mathbf{S})$ be the matrix variance statistic of the sum:

$$v(\mathbf{S}) := \left\| \mathbf{E}[\mathbf{S}\mathbf{S}^\top] \right\| \vee \left\| \mathbf{E}[\mathbf{S}^\top \mathbf{S}] \right\| = \left\| \sum_{k=1}^n \mathbf{E}[\mathbf{A}_k \mathbf{A}_k^\top] \right\| \vee \left\| \sum_{k=1}^n \mathbf{E}[\mathbf{A}_k^\top \mathbf{A}_k] \right\|. \quad (4.31)$$

Then

$$\left(\mathbf{E} \left[\|\mathbf{S}\|^2 \right] \right)^{\frac{1}{2}} \leq \sqrt{2ev(\mathbf{S}) \log(d_1 + d_2)} + 4e \left(\mathbf{E}[\max_{k \leq n} \|\mathbf{A}_k\|^2] \right)^{\frac{1}{2}} \log(d_1 + d_2). \quad (4.32)$$

Remark 4.1. Since $\mathbf{E}[\|S\|] \leq \mathbf{E}[\|S\|^2]^{\frac{1}{2}}$ by the Cauchy-Schwarz inequality, Theorem 4.4 also holds with $\mathbf{E}[\|S\|]$ on the left-hand side of (4.32). To obtain a tail bound we can employ the Markov inequality and Theorem 4.4:

$$\begin{aligned} \mathbf{P}[\|S\| \geq t] &\leq \frac{\mathbf{E}[\|S\|]}{t} \leq \frac{1}{t} \left(\sqrt{2ev(\mathbf{S}) \log(d_1 + d_2)} + 4e \left(\mathbf{E}[\max_{k \leq n} \|\mathbf{A}_k\|^2] \right)^{\frac{1}{2}} \log(d_1 + d_2) \right) \quad \text{for } t > 0. \end{aligned} \quad (4.33)$$

It might be possible to improve the log term employing an intrinsic dimension argument. \diamond

4.5 Intrinsic Dimension

Definition 4.5. For a positive-semidefinite matrix \mathbf{S} , the *intrinsic dimension* is the quantity

$$\text{intdim}(\mathbf{A}) := \frac{\text{tr} \mathbf{A}}{\|\mathbf{A}\|}.$$

Lemma 4.3. (Intrinsic dimension) Let $\varphi : [0, \infty) \rightarrow \mathbb{R}$ be a convex function with $\varphi(0) = 0$. For any positive-semidefinite matrix \mathbf{S} it holds that

$$\text{tr}(\varphi(\mathbf{S})) \leq \text{intdim}(\mathbf{S}) \cdot \varphi(\|\mathbf{S}\|).$$

Proof. [Tro15, Lemma 7.5.1] Since φ is convex on any interval $[0, L]$ with $L > 0$ and $\varphi(0) = 0$, it holds

$$\varphi(a) \leq \left(1 - \frac{a}{L}\right) \varphi(0) + \frac{a}{L} \varphi(L) = \frac{a}{L} \varphi(L) \quad \text{for all } a \in [0, L]. \quad (4.34)$$

Since \mathbf{S} is positive-semidefinite, the eigenvalues of \mathbf{S} fall in the interval $[0, L]$, where $L = \|\mathbf{S}\|$.

$$\mathrm{tr}(\varphi(\mathbf{S})) = \sum_{i=1}^d \varphi(\lambda_i) \leq \frac{\sum_{i=1}^d \lambda_i}{\|\mathbf{S}\|} \varphi(\|\mathbf{S}\|) = \frac{\mathrm{tr}(\mathbf{S})}{\|\mathbf{S}\|} \varphi(\|\mathbf{S}\|) = \mathrm{intdim}(\mathbf{S}) \cdot \varphi(\|\mathbf{S}\|). \quad (4.35)$$

5 Empirical Processes

5.1 A Primer on Empirical Processes

Let (\mathbb{D}, d) be a metric space, and let $(\mathbf{P}_n)_{n \in \mathbb{N}}$ be (Borel) probability measures on $(\mathbb{D}, \mathcal{D})$, where \mathcal{D} is the Borel σ -algebra on \mathbb{D} , the smallest σ -algebra containing all open sets. Then the sequence \mathbf{P}_n **converges weakly** to \mathbf{P} , which we denote as $\mathbf{P}_n \rightsquigarrow \mathbf{P}$, if and only if

$$\int_{\mathbb{D}} f d\mathbf{P}_n \rightarrow \int_{\mathbb{D}} f d\mathbf{P} \quad \text{for all } f \in C_b(\mathbb{D}). \quad (5.1)$$

Here $C_b(\mathbb{D})$ denotes the set of all bounded, continuous, real functions on \mathbb{D} . Equivalently, if X_n and X are \mathbb{D} -valued random variables with distribution \mathbf{P}_n and \mathbf{P} respectively, then $X_n \rightarrow X$ if and only if

$$\mathbf{E}[f(X_n)] \rightarrow \mathbf{E}[f(X)] \quad \text{for all } f \in C_b(\mathbb{D}). \quad (5.2)$$

This definitions yield the classical theory of weak convergence. For a modern treatment see [Kle20].

The classical theory requires that \mathbf{P}_n is defined, for each $n \in \mathbb{N}$, on the Borel σ -algebra \mathcal{D} , or, equivalently, that X_n is a Borel measurable map for each $n \in \mathbb{N}$. If $(\Omega_n, \mathcal{A}_n, \mathbf{P}_n)$ are the underlying probability spaces on which the maps X_n are defined, this means that $X_n^{-1}(D) \in \mathcal{A}_n$ for every Borel set $D \in \mathcal{D}$. This required measurability usually holds when \mathbb{D} is a separable metric space such as \mathbb{R}^k or $C([0, 1])$ with the supremum metric.

However, this apparently modest requirement can and does easily fail when the metric space \mathbb{D} is not separable.

Example 5.1. [vdvW13, Problem 1.7.3] Let $\mathbb{D} = D([0, 1])$ be the **Skorohod space** of all right-continuous functions on $[0, 1]$ with left limits endowed with the metric induced by the supremum norm. Define $X : [0, 1] \rightarrow \mathbb{D}$, $\omega \mapsto \mathbf{1}_{[\omega, 1]}$. If we equip $[0, 1]$ with the Borel σ -algebra $\mathcal{B}([0, 1])$, then X is not measurable. To see this, let B_s be the open ball of radius $1/2$ in \mathbb{D} around the function $\mathbf{1}_{[s, 1]}$. Now $X(\omega) \in B_s$ if and only if $\omega = s$. Indeed, if $\omega \neq s$ there exists an x between ω and s such that the difference of the indicator functions is 1 at x . Conversely, if

the distance is greater than $1/2$ at a point $x \in [0, 1]$, it is because x lies between ω and s and the indicator functions have difference 1. Since arbitrary (even uncountable) unions of open sets are open, we get for every $S \subseteq [0, 1]$ the open set $G := \bigcup_{s \in S} B_s \in \mathcal{D}$. It follows $X^{-1}(G) = S$ for all $S \subseteq [0, 1]$. Since not all subsets of $[0, 1]$ are measurable, we have $X^{-1}(\mathcal{D}) \not\subseteq \mathcal{B}([0, 1])$. But then X is not measurable. The σ -algebra \mathcal{D} is too large. \diamond

Let $(\Omega, \mathcal{A}, \mathbf{P})$ be a probability space and (\mathcal{X}, Σ) a measurable space. Let $X_j : (\Omega, \mathcal{A}, \mathbf{P}) \rightarrow (\mathcal{X}, \Sigma)$, $j = 1, \dots, n$ be independent and identically-distributed (i.i.d.) random variables with probability distribution \mathbf{P}_X and \mathcal{F} a family of measurable functions $f : (\mathcal{X}, \Sigma) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$. Consider the map

$$f \mapsto G_n f := \sqrt{n} \left(\frac{1}{n} \sum_{i=1}^n f(X_i) - \mathbf{P}_X f \right), \quad (5.3)$$

where $\mathbf{P}_X f := \int_{\mathcal{X}} f d\mathbf{P}_X$. We call $(G_n f)_{f \in \mathcal{F}}$ the empirical process indexed by \mathcal{F} . Furthermore

$$\|G_n f\|_{\mathcal{F}} := \sup_{f \in \mathcal{F}} |G_n f|. \quad (5.4)$$

5.2 Maximal Inequalities

Let $(\Omega, \mathcal{A}, \mathbf{P})$ be a probability space and (\mathcal{X}, Σ) a measurable space. Let $X_j : (\Omega, \mathcal{A}, \mathbf{P}) \rightarrow (\mathcal{X}, \Sigma)$, $j = 1, \dots, n$ be independent and identically-distributed (i.i.d.) random variables with probability distribution \mathbf{P}_X and \mathcal{F} a family of measurable functions $f : (\mathcal{X}, \Sigma) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$. Consider the map

$$f \mapsto G_n f := \sqrt{n} \left(\frac{1}{n} \sum_{i=1}^n f(X_i) - \mathbf{P}_X f \right), \quad (5.5)$$

where $\mathbf{P}_X f := \int_{\mathcal{X}} f d\mathbf{P}_X$. We call $(G_n f)_{f \in \mathcal{F}}$ the empirical process indexed by \mathcal{F} . Furthermore

$$\|G_n f\|_{\mathcal{F}} := \sup_{f \in \mathcal{F}} |G_n f|. \quad (5.6)$$

Lemma 5.1. (Bernstein Inequality for Empirical Processes) *For any bounded, measurable function f it holds for all $t > 0$*

$$\mathbf{P}(|G_n f| > t) \leq 2 \exp \left(-\frac{1}{4} \frac{t^2}{\mathbf{P}_X(f^2) + t \|f\|_{\infty} / \sqrt{n}} \right) \quad (5.7)$$

Proof. By the Markov inequality it holds for all $\lambda > 0$

$$\mathbf{P}(G_n f > t) \leq e^{-\lambda t} \mathbf{E} \exp(\lambda G_n f) \quad (5.8)$$

□

Lemma 5.2. *For any finite class \mathcal{F} of bounded, measurable, square-integrable functions, with $|\mathcal{F}|$ elements, it holds*

$$\mathbf{E} \|G_n f\|_{\mathcal{F}} \lesssim \max_{f \in \mathcal{F}} \frac{\|f\|_{\infty}}{\sqrt{n}} \log(1 + |\mathcal{F}|) + \max_{f \in \mathcal{F}} \|f\|_{\mathbf{P},2} \sqrt{\log(1 + |\mathcal{F}|)}. \quad (5.9)$$

Lemma 5.3. *For any class \mathcal{F} of measurable functions $f : \mathcal{X} \rightarrow \mathbb{R}$ such that $\mathbf{P}f^2 < \delta^2$ for every f , we have, with $a(\delta) = \delta / \sqrt{\text{Log} N_{[]}(\delta, \mathcal{F}, L_2(\mathbf{P}))}$, and F an envelope function,*

$$\mathbf{E}_{\mathbf{P}}^*[\|G_n\|_{\mathcal{F}}] \lesssim J_{[]}(\delta, \mathcal{F}, L_2(\mathbf{P})) + \sqrt{n} \mathbf{P}^* F \{F > \sqrt{n} a(\delta)\}. \quad (5.10)$$

Corollary 5.0.1. *For any class \mathcal{F} of measurable functions with envelope function F ,*

$$\mathbf{E}_{\mathbf{P}}^*[\|G_n\|_{\mathcal{F}}] \lesssim J_{[]}(\|F\|_{\mathbf{P},2}, \mathcal{F}, L_2(\mathbf{P})). \quad (5.11)$$

5.3 Functional Delta Method

Definition 5.1. *A map $\phi : \mathbb{D}_{\phi} \rightarrow \mathbb{E}$, defined on a subset \mathbb{D}_{ϕ} of a normed space \mathbb{D} that contains θ , is called **Hadamard differentiable** at θ if there exists a continuous, linear map $\phi'_{\theta} : \mathbb{D} \rightarrow \mathbb{E}$ such that*

$$\left\| \frac{\phi(\theta + th_t) - \phi(\theta)}{t} - \phi'_{\theta}(h) \right\|_{\mathbb{E}} \rightarrow 0 \quad \text{as } t \searrow 0 \text{ for all } h_t \rightarrow h \quad (5.12)$$

such that $\theta + th_t$ is contained in \mathbb{D}_{ϕ} for all small $t > 0$.

Theorem 5.1. (Delta Method) *Let \mathbb{D} and \mathbb{E} be normed linear spaces. Let $\phi : \mathbb{D}_{\phi} \subseteq \mathbb{D} \rightarrow \mathbb{E}$ be Hadamard differentiable at θ tangentially to \mathbb{D}_0 . Let $T_n : \Omega_n \rightarrow \mathbb{D}_{\phi}$ be maps such that $r_n(T_n - \theta) \rightsquigarrow T$ for some sequence of numbers $r_n \rightarrow \infty$ and a random element T that takes its values in \mathbb{D}_0 . Then $r_n(\phi(T_n) - \phi(\theta)) \rightsquigarrow \phi'_{\theta}(T)$. If ϕ'_{θ} is defined and continuous on the whole space \mathbb{D} , then we also have $r_n(\phi(T_n) - \phi(\theta)) = \phi'_{\theta}(r_n(T_n - \theta)) + o_{\mathbf{P}}(1)$.*

Proof. [vdV98, Theorem 20.8]

□

6 Simple yet useful Calculations

Theorem 6.1. (Multivariate Taylor Theorem) *Let $f \in C^2(\mathbb{R}^n, \mathbb{R})$. Then for all $x, \Delta \in \mathbb{R}^n$ there exists $\xi \in [0, 1]$ such that it holds*

$$\begin{aligned} f(x + \Delta) = & f(x) + \sum_{i=1}^n \frac{\partial f(x)}{\partial x_i} \Delta_i + \sum_{\substack{i,j=1 \\ i \neq j}}^n \frac{\partial^2 f(x + \xi \Delta)}{\partial x_i \partial x_j} \Delta_i \Delta_j \\ & + \frac{1}{2} \sum_{i=1}^n \frac{\partial^2 f(x + \xi \Delta)}{\partial x_i^2} \Delta_i^2 \end{aligned} \quad (6.1)$$

Corollary 6.1.1. *Let $f \in C^2(\mathbb{R})$. Then for all $a, x, \Delta \in \mathbb{R}^n$ there exist $\xi \in [0, 1]$ such that it holds*

$$f(a^T(x + \Delta)) - f(a^T x) = f'(a^T x) \Delta^T a + \frac{1}{2} f''(a^T(x + \xi \Delta)) \Delta^T A \Delta, \quad (6.2)$$

where $A := aa^T \in \mathbb{R}^{n \times n}$.

Proof. By the chain rule we have for all $a, x, \Delta \in \mathbb{R}^n$ and $\xi \in [0, 1]$

$$\frac{\partial^2 f(a^T(x + \xi \Delta))}{\partial x_i \partial x_j} = f''(a^T(x + \xi \Delta)) a_i a_j. \quad (6.3)$$

Since $A := aa^T$ is symmetric we have

$$\Delta^T A \Delta = 2 \sum_{\substack{i,j=1 \\ i \neq j}}^n a_i a_j \Delta_i \Delta_j + \sum_{i=1}^n a_i^2 \Delta_i^2. \quad (6.4)$$

Plugging (6.3) and (6.4) into (6.1) yields (6.2). \square

Proposition 6.1. *For all $x, y \in \mathbb{R}$ it holds*

$$|x + y| - |x| \geq -|y| \quad (6.5)$$

Proof. Checking all 6 combinations of $x + y, x, y$ being nonnegative or negative yields the result. \square

Notation Index

$\#A$ cardinality of the set A

$\mathbf{E}[X|Y]$ conditional expectation of the random variable X with respect to $\sigma(Y)$

$\mathbf{E}[X]$ expectation of the random variable X

$\mathbf{Var}[X]$ variance of the random variable X

$\overline{\mathbb{R}} = \mathbb{R} \cup \{+\infty\}$ extension of the real numbers

$\xrightarrow{\mathcal{D}}$ convergence of distributions

\mathbf{P} generic probability measure

$\mathbf{P}_X = \mathbf{P} \circ X^{-1}$ distribution of the random variable X

\mathbb{R} set of real numbers

$x \vee y, x \wedge y, x^+, x^-$ maximum, minimum, positive part, negative part of real numbers

$X \sim \mu$ the random variable has distribution μ
