Chapter 1

Chapter One Title

hello $\mathbb{R}$

Chapter 2

Convex Analysis

We begin by defining convex sets

Definition 1. *A subset $\Omega \subseteq \mathbb{R}^n$ is called CONVEX if we have $\lambda x + (1-\lambda)y \in \Omega$ for all $x, y \in \Omega$ and $\lambda \in (0,1)$.*

Clearly, the line segment $[a,b] := \{\lambda a + (1-\lambda)b \mid \lambda \in [0,1]\}$ is contained in Ω for all $a, b \in \Omega$ if and only if Ω is a convex set.

Next we define convex functions.

The concept of convex functions is closely related to convex sets.

The line segment between two points on the graph of a convex function lies on or above and does not intersect the graph.

In other words: The area above the graph of a convex function f is a convex set, i.e. the *epigraph* $\text{epi}(f) := \{(x, \alpha) \in \mathbb{R}^n \times \mathbb{R} \mid f(x) \leq \alpha\}$ is a convex set in $\mathbb{R}^{n+1}$.

Often an equivalent characterisation of convex functions is more useful.

Theorem 1. *The convexity of a function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ on $\mathbb{R}^n$ is equivalent to the following statement:*

For all $x, y \in \mathbb{R}^n$ and $\lambda \in (0,1)$ we have

$$f(\lambda x + (1-\lambda)y) \leq \lambda f(x) + (1-\lambda)f(y). \tag{2.1}$$

Chapter 3

Random Matrix Inequality

Theorem 2. *Let* $(A_k)_{1 \leq k \leq n} \subseteq \mathbb{R}^{d_1 \times d_2}$ *be a finite sequence of independent, random matrices. Assume that*

$$\mathbb{E}(A_k) = 0 \quad and \quad \|A_k\| \leq L \quad for \ each \quad k \in \{1, \ldots, n\}. \qquad (3.1)$$

Introduce the random matrix

$$S := \sum_{k=1}^{n} A_k. \qquad (3.2)$$

Let $v(S)$ *be the matrix variance statistic of the sum:*

$$v(S) := \max\left\{\left\|\mathbb{E}(SS^T)\right\|, \left\|\mathbb{E}(S^T S)\right\|\right\} \qquad (3.3)$$

$$= \max\left\{\left\|\sum_{k=1}^{n} \mathbb{E}(A_k A_k^T)\right\|, \left\|\sum_{k=1}^{n} \mathbb{E}(A_k^T A_k)\right\|\right\}. \qquad (3.4)$$

Then

$$\mathbb{E}\|S\| \leq \sqrt{2v(S)\log(d_1 + d_2)} + \frac{1}{3}L\log(d_1 + d_2). \qquad (3.5)$$

Furthermore, for all $t \geq 0$,

$$\mathbb{P}(\|S\| \geq t) \geq (d_1 + d_2)\exp\left(\frac{-t^2/2}{v(S) + Lt/3}\right). \qquad (3.6)$$

Chapter 4

Simple yet useful Calculations

Proposition 1. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be continuous such that a minimum x^* exists and is unique. Then for all $y \in \mathbb{R}^n$ and $C > 0$ it follows*

$$\inf_{\|\Delta\|=C} f(y + \Delta) - f(y) > 0 \qquad \Rightarrow \qquad \|x^* - y\| \leq C. \qquad (4.1)$$

Proof. Since $\mathcal{C} := \{\|\Delta\| \leq C\}$ is compact and

$$f(x^*) \leq f(y) < \inf_{\|\Delta\|=C} f(y + \Delta)$$

the continious function $f(y + \,\cdot\,)$ has a minimum in $\overset{\circ}{\mathcal{C}} := \{\|\Delta\| < C\}$. Since x^* is the unique minimum of f there exists $\Delta^* \in \overset{\circ}{\mathcal{C}}$ such that $x^* - y = \Delta^*$. We conclude that $\|x^* - y\| \leq C$. $\qquad\qquad\square$
